Project P3 Reinforcement learning out soon

Outline

- ♦ P2 Mini Contest Winners!
- \diamondsuit Reinforcement Learning Recap
- \diamondsuit Evaluation Functions
- \diamondsuit Linear Feature Functions
- \diamondsuit Function Approximation

Credit to Dan Klein, Stuart Russell and Andrew Moore for most of today's slides

P2 Mini Contest Winners!

3rd: Leonard Komow - Wins: 4, Timeouts: 0, Crashes: 0, Average: 1868.33

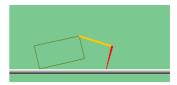

2nd: Eliot Glairon - Wins: 2, Timeouts: 0, Crashes: 0, Average: 2281.83

1st: Dylan Klein and Justin Baacke Wins: 6, Timeouts: 0, Crashes: 0, Average: 3419.50

Reinforcement Learning

Reinforcement learning:

- Still assume an MDP:
 - A set of states s ∈ S
 - A set of actions (per state) A
 - A model T(s,a,s')
 - A reward function R(s,a,s')
- Still looking for a policy $\pi(s)$

[DEMO]

- New twist: don't know T or R
 - I.e. don't know which states are good or what the actions do
 - Must actually try actions and states out to learn

The Story So Far: MDPs and RL

Things we know how to do:

- If we know the MDP
 - Compute V*, Q*, π* exactly
 - Evaluate a fixed policy π
- If we don't know the MDP
 - We can estimate the MDP then solve
 - We can estimate V for a fixed policy π
 - We can estimate Q*(s,a) for the optimal policy while executing an exploration policy

Techniques:

- Model-based DPs
 - Value and policy Iteration
 - Policy evaluation
- Model-based RL
- Model-free RL:
 - Value learning
 - Q-learning

Model-Free Learning

- Model-free (temporal difference) learning
 - Experience world through episodes

 $(s, a, r, s', a', r', s'', a'', r'', s'''' \dots)$

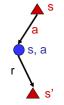

- Update estimates each transition (s, a, r, s')
- Over time, updates will mimic Bellman updates

Q-Value Iteration (model-based, requires known MDP)

$$Q_{i+1}(s,a) \leftarrow \sum_{s'} T(s,a,s') \left[R(s,a,s') + \gamma \max_{a'} Q_i(s',a') \right]$$

Q-Learning (model-free, requires only experienced transitions)

$$Q(s,a) \leftarrow (1-\alpha)Q(s,a) + (\alpha) \left[r + \gamma \max_{a'} Q(s',a') \right]$$

[DEMO - Grid Q's]

Q-Learning

We'd like to do Q-value updates to each Q-state:

 $Q_{i+1}(s,a) \leftarrow \sum_{s'} T(s,a,s') \left[R(s,a,s') + \gamma \max_{a'} Q_i(s',a') \right]$

But can't compute this update without knowing T, R

- Instead, compute average as we go
 - Receive a sample transition (s,a,r,s')
 - This sample suggests

 $Q(s,a) \approx r + \gamma \max_{a'} Q(s',a')$

- But we want to average over results from (s,a) (Why?)
- So keep a running average

 $Q(s,a) \leftarrow (1-\alpha)Q(s,a) + (\alpha)\left[r + \gamma \max_{a'} Q(s',a')\right]$

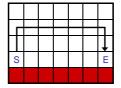

[DEMO - Grid Q's]

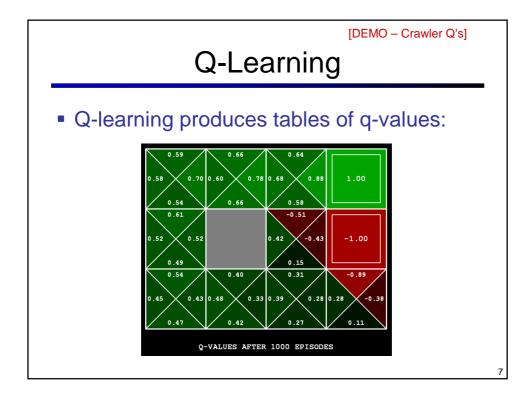

Q-Learning Properties

Will converge to optimal policy

- If you explore enough (i.e. visit each q-state many times)
- If you make the learning rate small enough
- Basically doesn't matter how you select actions (!)
- Off-policy learning: learns optimal q-values, not the values of the policy you are following

Exploration / Exploitation

Several schemes for forcing exploration

- Simplest: random actions (ε greedy)
 - Every time step, flip a coin
 - With probability ε, act randomly
 - With probability 1-ε, act according to current policy
- Regret: expected gap between rewards during learning and rewards from optimal action
 - Q-learning with random actions will converge to optimal values, but possibly very slowly, and will get low rewards on the way
 - Results will be optimal but regret will be large
 - How to make regret small?

[DEMO - Crawler]

Exploration Functions

When to explore

- Random actions: explore a fixed amount
- Better ideas: explore areas whose badness is not (yet) established, explore less over time
- One way: exploration function
 - Takes a value estimate and a count, and returns an optimistic utility, e.g. f(u, n) = u + k/n (exact form not important)

$$Q_{i+1}(s,a) \leftarrow_{\alpha} R(s,a,s') + \gamma \max_{a'} Q_i(s',a')$$
$$Q_{i+1}(s,a) \leftarrow_{\alpha} R(s,a,s') + \gamma \max_{a'} f(Q_i(s',a'), N(s',a'))$$

Q-Learning

- In realistic situations, we cannot possibly learn about every single state!
 - Too many states to visit them all in training
 - Too many states to hold the q-tables in memory
- Instead, we want to generalize:
 - Learn about some small number of training states from experience
 - Generalize that experience to new, similar states
 - This is a fundamental idea in machine learning, and we'll see it over and over again

[DEMO - RL Pacman]

Example: Pacman

- Let's say we discover through experience that this state is bad:
- In naïve q learning, we know nothing about this state or its q states:

Or even this one!

Feature-Based Representations

- Solution: describe a state using a vector of features (properties)
 - Features are functions from states to real numbers (often 0/1) that capture important properties of the state
 - Example features:
 - Distance to closest ghost
 - Distance to closest dot
 - Number of ghosts
 - 1 / (dist to dot)²
 - Is Pacman in a tunnel? (0/1)
 - etc.
 - Is it the exact state on this slide?
 - Can also describe a q-state (s, a) with features (e.g. action moves closer to food)

Linear Feature Functions

 Using a feature representation, we can write a q function (or value function) for any state using a few weights:

$$V(s) = w_1 f_1(s) + w_2 f_2(s) + \ldots + w_n f_n(s)$$

 $Q(s,a) = w_1 f_1(s,a) + w_2 f_2(s,a) + \ldots + w_n f_n(s,a)$

- Advantage: our experience is summed up in a few powerful numbers
- Disadvantage: states may share features but actually be very different in value!

Function Approximation

$$Q(s,a) = w_1 f_1(s,a) + w_2 f_2(s,a) + \ldots + w_n f_n(s,a)$$

Q-learning with linear q-functions:

 $\begin{aligned} transition &= (s, a, r, s') \\ \text{difference} &= \left[r + \gamma \max_{a'} Q(s', a') \right] - Q(s, a) \\ Q(s, a) &\leftarrow Q(s, a) + \alpha \text{ [difference]} & \text{Exact Q's} \\ w_i &\leftarrow w_i + \alpha \text{ [difference]} f_i(s, a) & \text{Approximate Q's} \end{aligned}$

- Intuitive interpretation:
 - Adjust weights of active features
 - E.g. if something unexpectedly bad happens, disprefer all states with that state's features
- Formal justification: online least squares

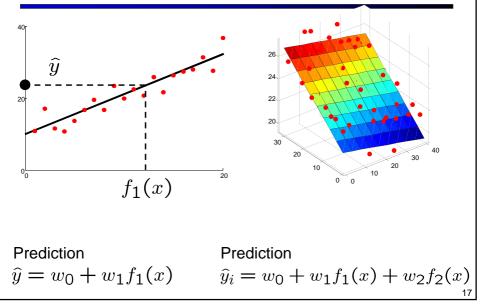

[DEMO - RL Pacman]

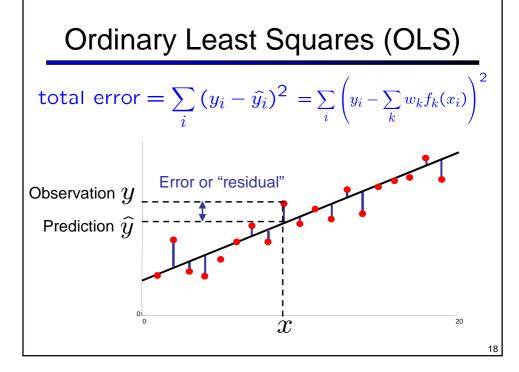

Example: Q-Pacman

$Q(s,a) = 4.0 f_{DOT}(s,a) - 1.0 f_{GST}(s,a)$
$f_{DOT}(s, \text{NORTH}) = 0.5$
$f_{GST}(s, \text{NORTH}) = 1.0$
Q(s,a) = +1
R(s,a,s') = -500
difference = -501
$w_{DOT} \leftarrow 4.0 + \alpha \left[-501\right] 0.5$
$w_{GST} \leftarrow -1.0 + \alpha \left[-501 ight] 1.0$
$Q(s,a) = 3.0 f_{DOT}(s,a) - 3.0 f_{GST}(s,a)$

Linear Regression

Minimizing Error

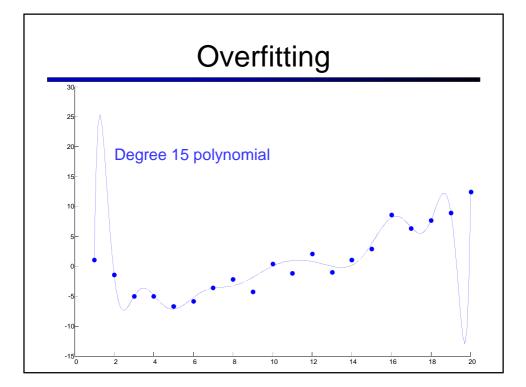

Imagine we had only one point x with features f(x):

$$\operatorname{error}(w) = \frac{1}{2} \left(y - \sum_{k} w_{k} f_{k}(x) \right)^{2}$$
$$\frac{\partial \operatorname{error}(w)}{\partial w_{m}} = - \left(y - \sum_{k} w_{k} f_{k}(x) \right) f_{m}(x)$$
$$w_{m} \leftarrow w_{m} + \alpha \left(y - \sum_{k} w_{k} f_{k}(x) \right) f_{m}(x)$$

Approximate q update explained:

"target" "prediction"

$$w_m \leftarrow w_m + \alpha \left[r + \gamma \max_a Q(s', a') - Q(s, a) \right] f_m(s, a)$$

[DEMO]

Policy Search

Policy Search

- Problem: often the feature-based policies that work well aren't the ones that approximate V / Q best
 - E.g. your value functions from project 2 were probably horrible estimates of future rewards, but they still produced good decisions
 - We'll see this distinction between modeling and prediction again later in the course
- Solution: learn the policy that maximizes rewards rather than the value that predicts rewards
- This is the idea behind policy search, such as what controlled the upside-down helicopter

Policy Search

Simplest policy search:

- Start with an initial linear value function or q-function
- Nudge each feature weight up and down and see if your policy is better than before

Problems:

- How do we tell the policy got better?
- Need to run many sample episodes!
- If there are a lot of features, this can be impractical

Policy Search*

- Advanced policy search:
 - Write a stochastic (soft) policy:

 $\pi_w(s) \propto e^{\sum_i w_i f_i(s,a)}$

- Turns out you can efficiently approximate the derivative of the returns with respect to the parameters w (optional material)
- Take uphill steps, recalculate derivatives, etc.

Take a Deep Breath...

- We're done with search and planning!
- Next, we'll look at how to reason with probabilities
 - Diagnosis
 - Tracking objects
 - Speech recognition
 - Robot mapping
 - Interpretended in the second secon

Last part of course: machine learning
