

Course segments

1) Probabilistic reasoning

Ex: medical diagnosis

Knowledge representation: diseases cause symptoms

Modeling uncertainty: some diseases, symptoms more likely than others

Reasoning: infer diseases from symptoms

Probability: quantitative, self-consistent framework that captures commonsense patterns of reasoning

graphical model - how do graphs represent correlation, causation, statistical independence?

Marriage of probability and graph theory

Classification Ex: spam filtering in e-mail.

input: email message

output: {spam, non-spam}

How to represent the input?

Convert text to vector of word counts:

c_i = count # times i^{th} word in email

V = vocabulary size

dictionary

Certain words more likely in spam.
How to quantify? Estimate?

Sequential modeling

How to model systems where "state" changes over time (or has a similarly extended representation)?

Ex: text (written language)

"state" = word

Which sentence is more likely?

- ① Mary had a little lamb.
- ② colorless green ideas sleep furiously.

⇒ Markov models of statistical language processing

w_t = word at t^{th} position in sentence (with V possible values)

Graphical models

Model A is rich but harder to estimate.

Model B is obviously wrong, over-simplified but easier to estimate.

Tradeoff: $\left\{ \begin{array}{l} \text{power} \\ \text{expressiveness} \end{array} \right\}$ vs $\left\{ \begin{array}{l} \text{tractability} \\ \text{learning} \end{array} \right\}$

Ex: speech (spoken language)

states = words (or syllables or smaller units of speech)

observations = sounds, waveforms

How to infer words from waveforms?

⇒ hidden Markov models for speech recognition

Planning and decision-making

Ex: robot navigation

enter

2D grid world

- "states" = cells of grid
- actions = north, south, east, west
- noisy dynamics in world

learning = feedback from environment

$\left\{ \begin{array}{l} \text{delayed vs immediate} \\ \text{evaluative vs instructive} \end{array} \right\}$

More generally: how can autonomous agents learn from experience?

⇒ Markov decision processes
Reinforcement learning

Other "embodied" agents: helicopter, elevators

Other "embedded" agents: game playing agents AI, telephone operators

Core ideas of modern AI

- 1) Probabilistic models of uncertainty
- 2) learning as optimization

Variable θ parametrizes agent's model / predictions / behaviors.
Function $f(\theta)$ measures agent's performance.

3) Knowledge as predictions (dynamics) not facts (static)

- classical AI

 - fact # 1 : canaries are birds

 - fact # 2 : a bird is on the table

- modern, agent-centric AI

 - prediction: if action a , then observe consequence with same probability.
