

An Overview of Integer Factorization Algorithms

NAKKUL SREENIVAS

Practical Applications and Uses

- ▶ Primes are the basis of modern day encryption schemes. Why?
 - ▶ No factors which makes it harder to decrypt without knowing the exact prime value. Refer to Polyalphabetic cipher
 - ▶ Fewer collisions when encrypting.
 - ▶ Hard to generate large primes (with exception of certain special primes i.e. Mersenne Primes etc.)
- ▶ For most intents and purposes prime factorization is the same problem as prime generation.
- ▶ Used for public key generation (RSA encryption) by multiplying two large primes with one being a key.

Types of Algorithms

- ▶ Category 1
 - ▶ Pollards Rho, Fermat, Euler
- ▶ Category 2
 - ▶ Dixons, GNFS, Quadratic, Shanks
- ▶ Special Cases
 - ▶ Shor's

Upper bound for Worst Case Runtime

- ▶ Runtime based on size of integer **N**.
- ▶ Brute force (Sieve of Erastosthenes) gives a lower bound of \sqrt{n} .
- ▶ Include basic optimizations of the sieve $\sqrt{n}/\log(n)$.
 - ▶ Store in table
 - ▶ Start at the square of the number

1?	2	3	4	5	6	7	8	9	10
11	12	13	14	15	16	17	18	19	20
21	22	23	24	25	26	27	28	29	30
31	32	33	34	35	36	37	38	39	40
41	42	43	44	45	46	47	48	49	50
51	52	53	54	55	56	57	58	59	60
61	62	63	64	65	66	67	68	69	70
71	72	73	74	75	76	77	78	79	80
81	82	83	84	85	86	87	88	89	90
91	92	93	94	95	96	97	98	99	100

Numbers that divide by 2 in GREEN
Numbers that divide by 3 in BLUE
Numbers that divide by 5 in ORANGE
Numbers that divide by 7 in PURPLE

Quadratic Sieve

- ▶ Fermat's Factorization method
- ▶ Searching for values of **p** and **q**.
- ▶ Comparative speed and run time:
 - ▶ $O(e^{\sqrt{\ln(n) \ln(\ln(n))}})$
 - ▶ Fastest algorithm for numbers up to about 10^{100}

$$\begin{aligned} N &= 255 \\ \therefore a &= \sqrt{255} = 15.9687... = 16 \\ b &= \sqrt{a^2 - N} \\ \therefore b &= \sqrt{256 - 255} \\ \therefore b &= 1 \\ a + b &= 17 \\ a - b &= 15 \end{aligned}$$

General Number Field Sieve

- ▶ Works similar to the quadratic sieve
- ▶ Includes an optimal strategy for choosing p and q using **smooth numbers**
- ▶ Assigns each number to a vector given its prime factorization.
 - ▶ Uses these numbers to search for the proper p and q in form using linear algebra (matrix reduction)
- ▶ Computationally very intensive
- ▶ Requires huge amounts of memory but is faster for extremely large values of n .

Non-Sieve Algorithms

- ▶ CFRAC –Lehmer and Powers
- ▶ Dixon's- John D. Dixon
 - ▶ Uses a weaker assumption but with limitations
- ▶ Shanks' Method (congruence of squares and Fermat's)

Alternate Algorithms

- ▶ Other algorithms can be useful for reasons apart from cryptography
- ▶ If not searching for a number comprised of two large primes, can use a category 1 algorithm
- ▶ Most calculators use a variant of Pollard Rho's algorithm.
- ▶ Other methods include Fermats and Euler's methods.

Recent Advancements

- ▶ Three Taiwanese mathematicians developed a variant of Fermat's algorithm to search for factors in a more efficient manner.
- ▶ Used the technique of continued fractions and optimized a method to eliminate loop counts.
- ▶ Success rate of approximately 81.7% with large composite numbers.
