Machine Learning for Signal Processing

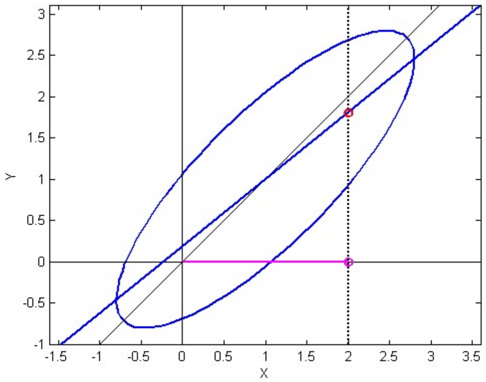
Predicting and Estimation from Time Series

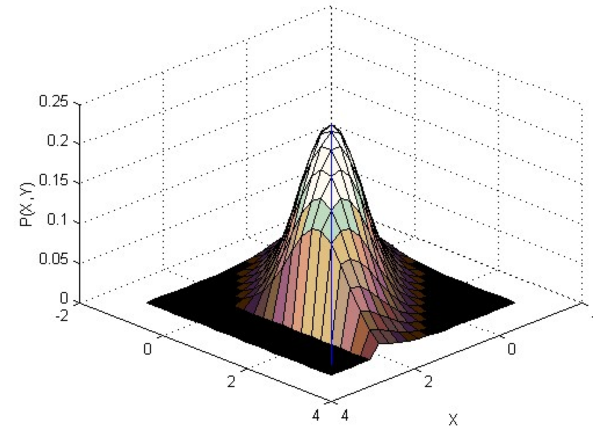
Bhiksha Raj

Preliminaries : P(y|x) for Gaussian

- If P(x,y) is Gaussian:

$$P(\mathbf{x},\mathbf{y}) = N\left(\begin{bmatrix}\mu_{\mathbf{x}} \\ \mu_{\mathbf{y}}\end{bmatrix}, \begin{bmatrix}C_{\mathbf{xx}} & C_{\mathbf{xy}} \\ C_{\mathbf{yx}} & C_{\mathbf{yy}}\end{bmatrix}\right)$$





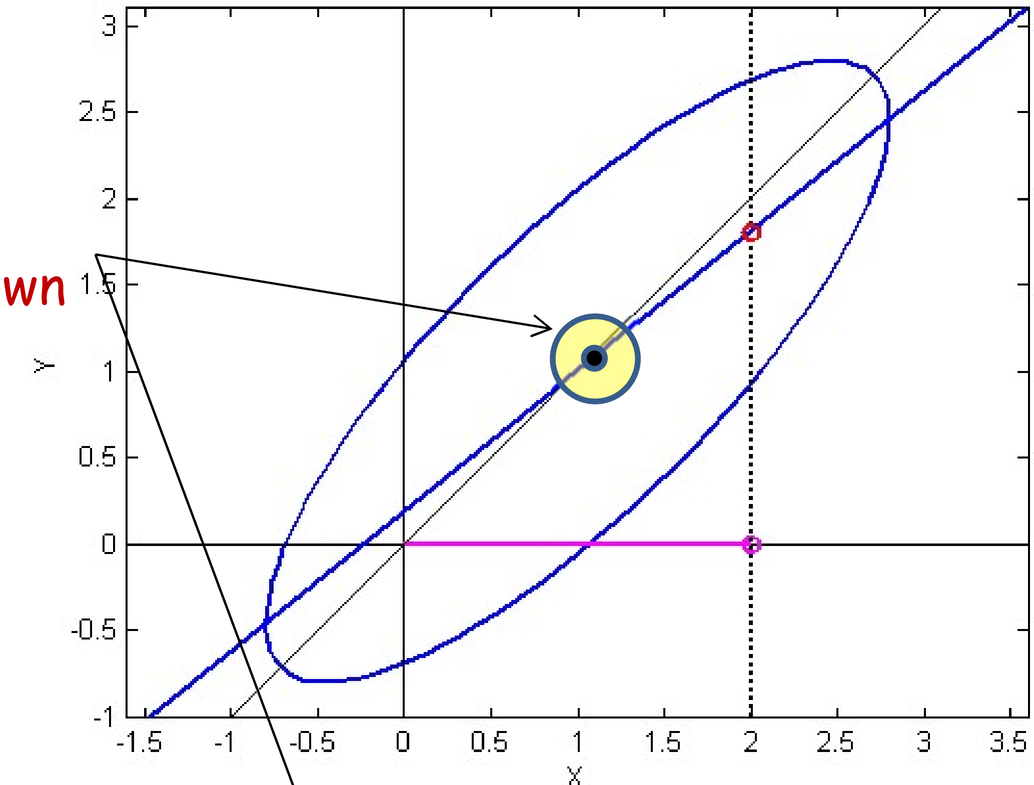
- The conditional probability of y given x is also Gaussian
  - The slice in the figure is Gaussian

$$P(y\,|\,x) = N(\mu_y + C_{yx}C_{xx}^{-1}(x-\mu_x), C_{yy} - C_{yx}C_{xx}^{-1}C_{xy})$$

- The mean of this Gaussian is a function of x
- The variance of y reduces if x is known
  - Uncertainty is reduced

Preliminaries : P(y|x) for Gaussian

Best guess for Y
when X is not known



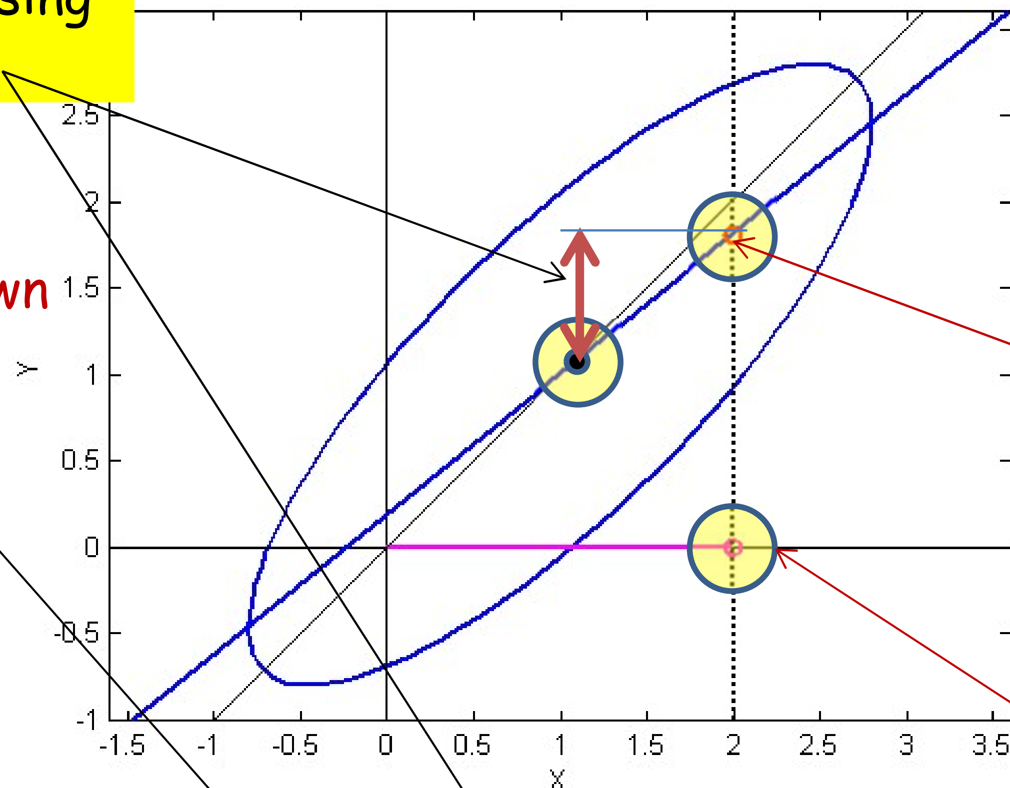
$$P(y \mid x) = N(\mu_y + C_{yx}C_{xx}^{-1}(x - \mu_x), C_{yy} - C_{yx}C_{xx}^{-1}C_{xy})$$

Preliminaries : P(y|x) for Gaussian

Update guess of Y based on information in X
Correction is 0 if X and Y are uncorrelated, i.e $C_{yx} = 0$

Correction of Y using information in X

Best guess for Y when X is not known



Mean of Y given X

Given X value

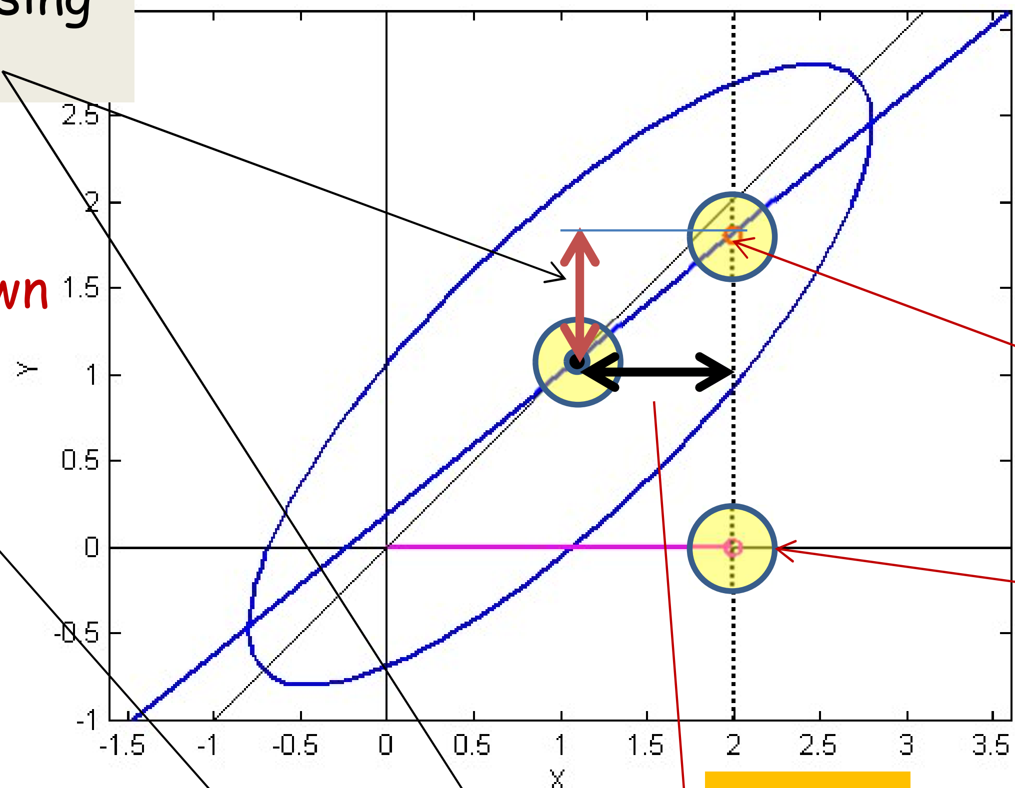
$$P(y \mid x) = N(\mu_y + C_{yx} C_{xx}^{-1} (x - \mu_x), C_{yy} - C_{yx} C_{xx}^{-1} C_{xy})$$

Preliminaries : P(y|x) for Gaussian

Correction to Y = slope * (offset of X from mean)

Correction of Y using information in X

Best guess for Y when X is not known



Mean of Y given X

Given X value

offset

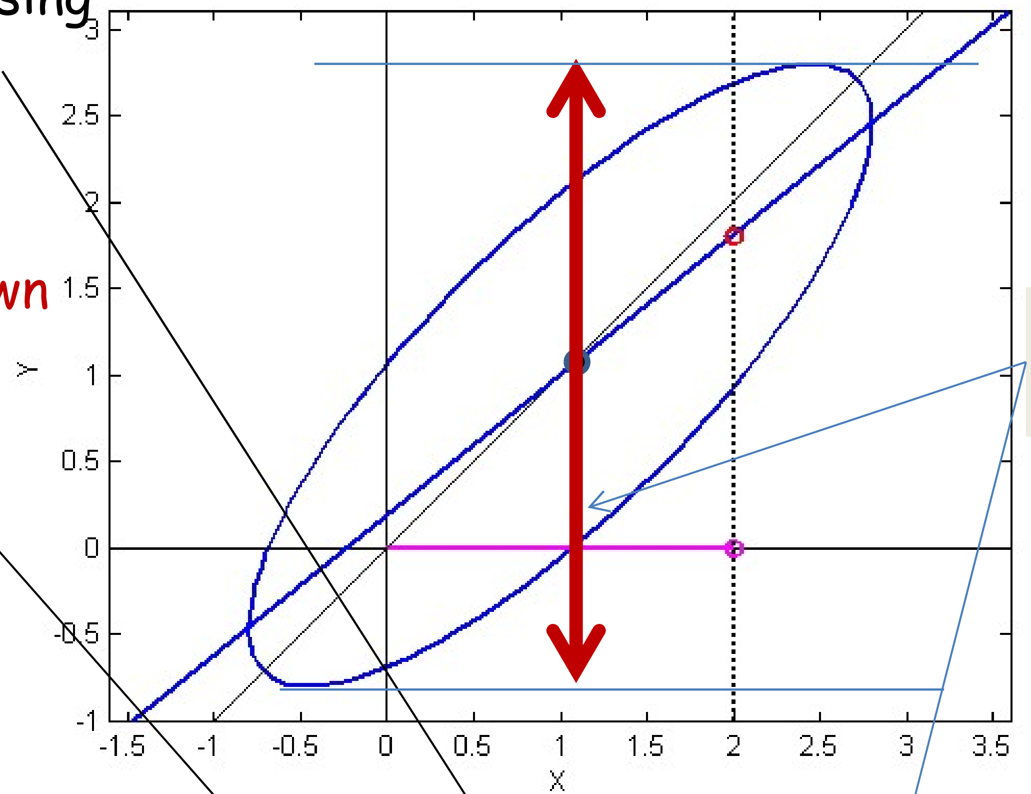
$$P(y\,|\,x) = N(\mu_y + C_{yx}C_{xx}^{-1}(x-\mu_x), C_{yy} - C_{yx}C_{xx}^{-1}C_{xy})$$

Slope

Preliminaries : P(y|x) for Gaussian

Correction of Y using information in X

Best guess for Y when X is not known



Uncertainty in Y when X is not known

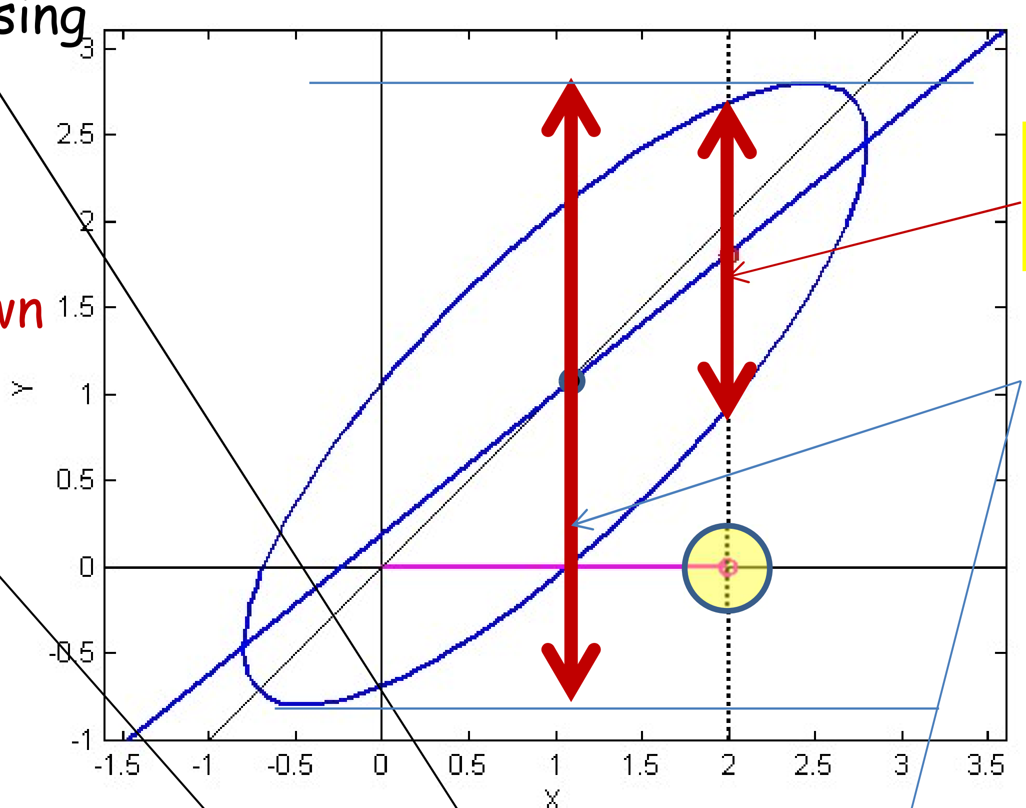
$$P(y \mid x) = N(\mu_y + C_{yx}C_{xx}^{-1}(x-\mu_x), C_{yy} - C_{yx}C_{xx}^{-1}C_{xy})$$

Preliminaries : P(y|x) for Gaussian

Shrinkage of variance is 0 if X and Y are uncorrelated, i.e $C_{yx} = 0$

Correction of Y using information in X

Best guess for Y when X is not known



Reduced uncertainty from knowing X

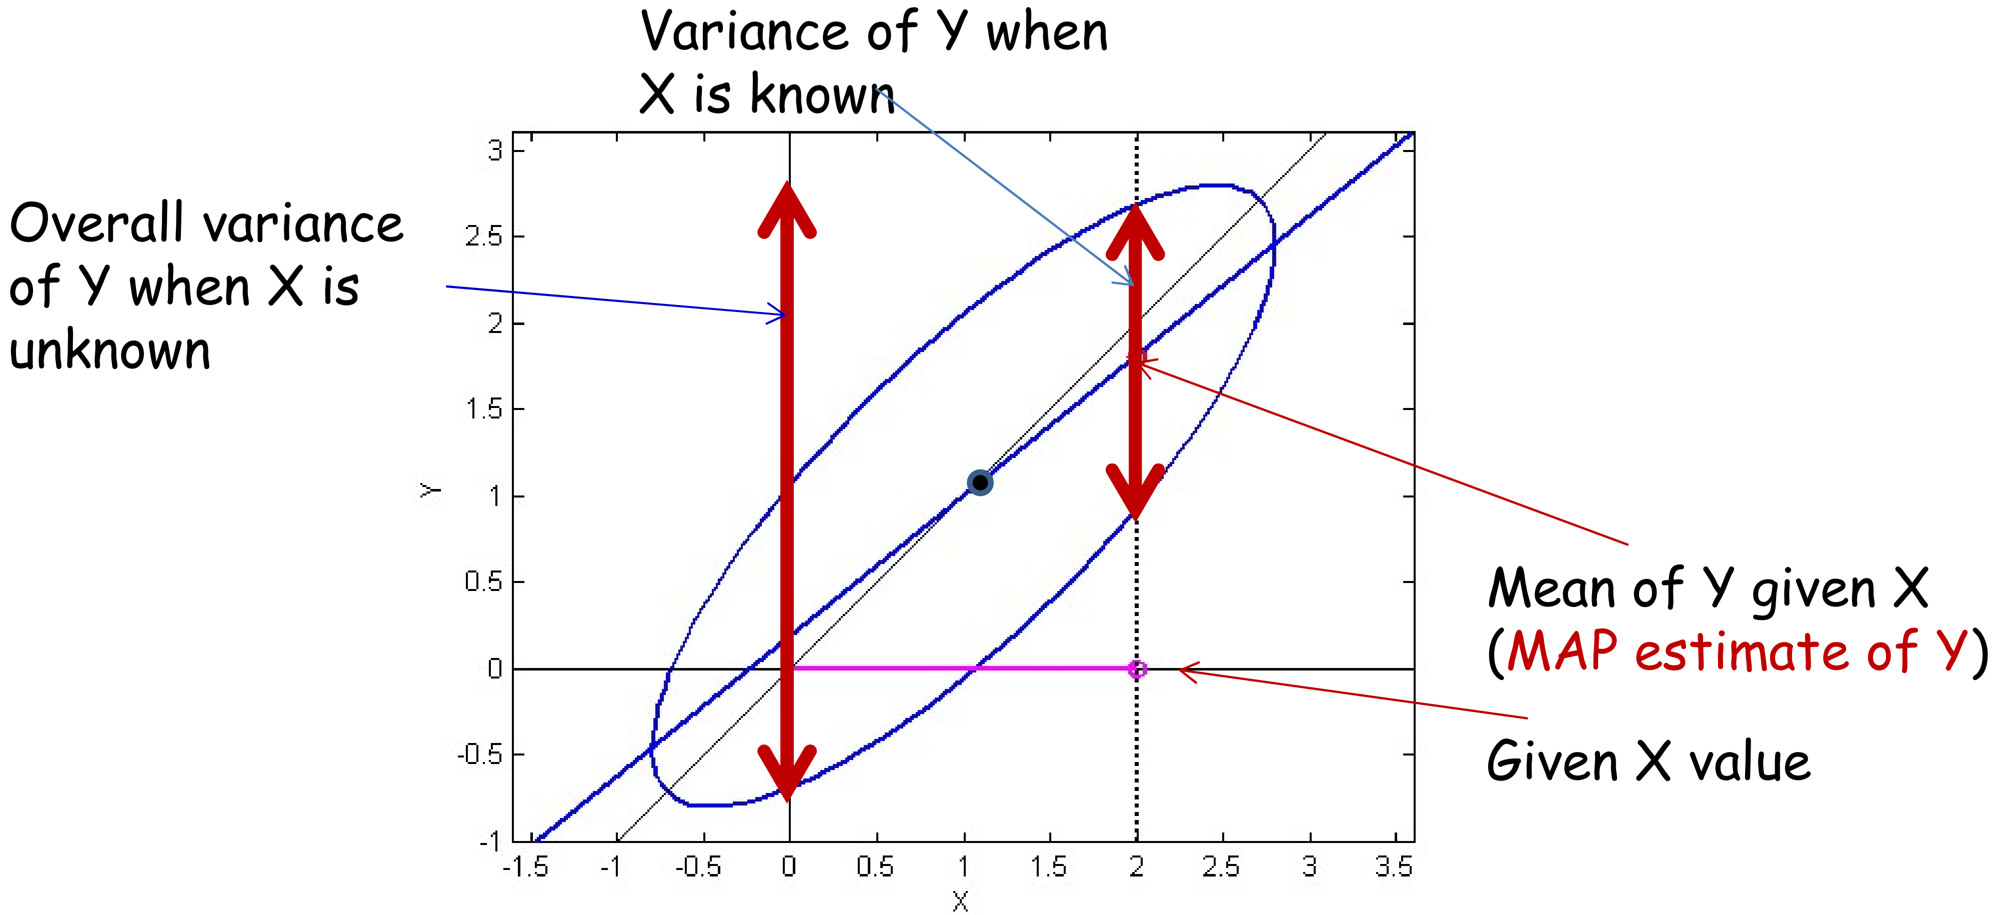
Uncertainty in Y when X is not known

Shrinkage of uncertainty from knowing X

$$P(y \mid x) = N(\mu_y + C_{yx}C_{xx}^{-1}(x-\mu_x), C_{yy} - \overline{C_{yx}C_{xx}^{-1}C_{xy}})$$

Preliminaries : P(y|x) for Gaussian

Knowing X modifies the mean of Y and shrinks its variance



$$P(y \mid x) = N(\mu_y + C_{yx}C_{xx}^{-1}(x - \mu_x), C_{yy} - C_{yx}C_{xx}^{-1}C_{xy})$$

Background: Sum of Gaussian RVs

$$O = AS + \varepsilon$$

$$S \sim N(\mu_s, \Theta_s) \qquad \varepsilon \sim N(\mu_\varepsilon, \Theta_\varepsilon)$$

- Consider a random variable *O* obtained as above

- The expected value of *O* is given by

$$E[O] = E[AS + \varepsilon] = A\mu_s + \mu_\varepsilon$$

- Notation:

$$E[O] = \mu_O$$

Background: Sum of Gaussian RVs

$$\boldsymbol{O} = \boldsymbol{AS} + \boldsymbol{\varepsilon}$$

$$\boldsymbol{S} \sim N(\boldsymbol{\mu_S}, \boldsymbol{\Theta_S}) \qquad \boldsymbol{\varepsilon} \sim N(\boldsymbol{\mu_\varepsilon}, \boldsymbol{\Theta_\varepsilon})$$

- The variance of *O* is given by

$$Var(\boldsymbol{O}) = \boldsymbol{\Theta_O} = \boldsymbol{E}\left[(\boldsymbol{O} - \boldsymbol{\mu_O})(\boldsymbol{O} - \boldsymbol{\mu_O})^T\right]$$

- This is just the sum of the variance of $\boldsymbol{AS}$ and the variance of $\boldsymbol{\varepsilon}$

$$\boldsymbol{\Theta_O} = \boldsymbol{A\Theta_S A}^{\mathrm{T}} + \boldsymbol{\Theta_\varepsilon}$$

Background: Sum of Gaussian RVs

$$O = AS + \varepsilon$$

$$S \sim N(\mu_S, \Theta_S) \qquad\qquad \varepsilon \sim N(\mu_\varepsilon, \Theta_\varepsilon)$$

- The conditional probability of *O*:

$$\boxed{P(O|S) = N(AS + \mu_\varepsilon, \Theta_\varepsilon)}$$

- The overall probability of *O*:

$$\boxed{P(O) = N(A\mu_s + \mu_\varepsilon, A\Theta_S A^{\mathrm{T}} + \Theta_\varepsilon)}$$

Background: Sum of Gaussian RVs

$$O = AS + \varepsilon$$

$$S \sim N(\mu_s, \Theta_s) \qquad \varepsilon \sim N(\mu_\varepsilon, \Theta_\varepsilon)$$

- The *cross-correlation* between *O* and *S*

$$\Theta_{OS} = E\left[(O - \mu_O)(S - \mu_s)^T\right] = E\left[(A(S - \mu_s) + (\varepsilon - \mu_\varepsilon))(S - \mu_s)^T\right]$$

$$= E\left[A(S - \mu_s)(S - \mu_s)^T + (\varepsilon - \mu_\varepsilon)(S - \mu_s)^T\right]$$

$$= AE\left[(S - \mu_s)(S - \mu_s)^T\right] + E\left[(\varepsilon - \mu_\varepsilon)(S - \mu_s)^T\right]$$

$$= AE\left[(S - \mu_s)(S - \mu_s)^T\right]$$

- $= A\,\Theta_s$

- The cross-correlation between *O* and *S* is

$$\Theta_{OS} = A\Theta_S$$

$$\Theta_{SO} = \Theta_S A^T$$

Background: Joint Prob. of O and S

$$O = AS + \varepsilon \qquad Z = \begin{bmatrix} O \\ S \end{bmatrix}$$

- The joint probability of *O* and *S* (i.e. P(*Z*)) is also Gaussian

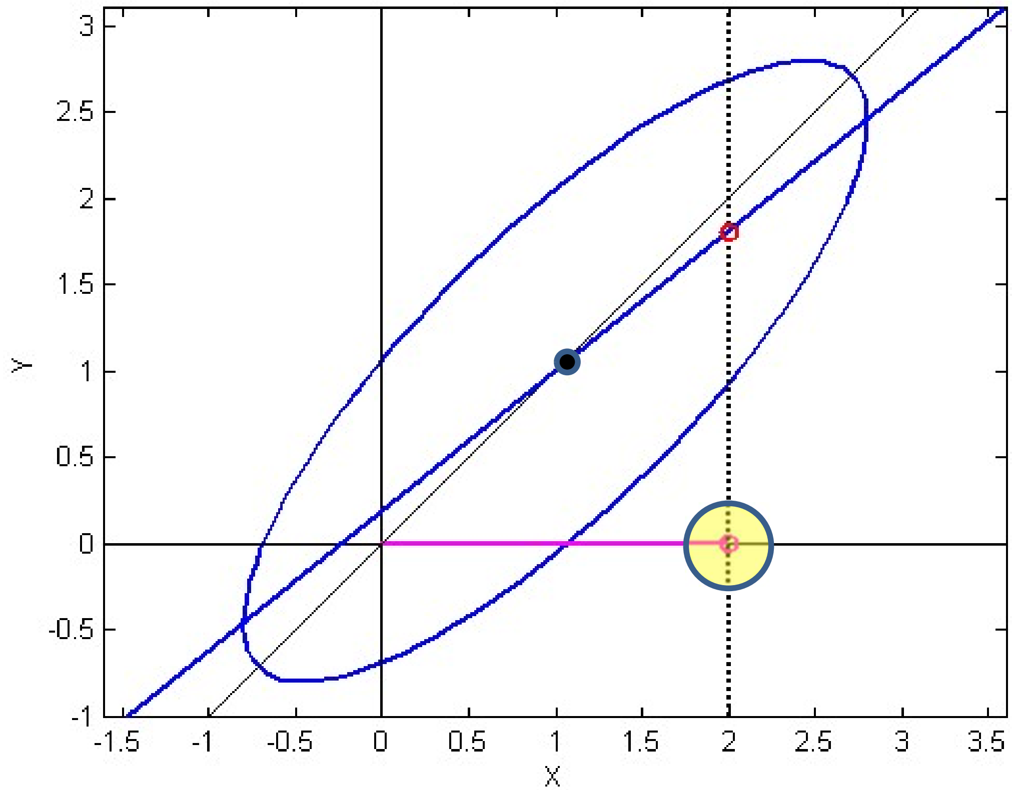
$$P(Z) = P(O, S) = N(\mu_Z, \Theta_Z)$$

- Where

$$\mu_Z = \begin{bmatrix} \mu_O \\ \mu_S \end{bmatrix} = \begin{bmatrix} A\mu_s + \mu_\varepsilon \\ \mu_S \end{bmatrix}$$

- $\Theta_Z = \begin{bmatrix} \Theta_O & \Theta_{OS} \\ \Theta_{SO} & \Theta_S \end{bmatrix} = \begin{bmatrix} A\Theta_S A^{\mathrm{T}} + \Theta_\varepsilon & A\Theta_S \\ \Theta_S A^{\mathrm{T}} & \Theta_S \end{bmatrix}$

Preliminaries : Conditional of S given O: P(S|O)



$$O = AS + \varepsilon$$

$$P(S|O) = N(\mu_S + \Theta_{SO}\Theta_O^{-1}(O - \mu_O),\ \ \Theta_S - \Theta_{SO}\Theta_O^{-1}\Theta_{OS})$$

$$P(S|O) = N(\mu_S + \Theta_S A^{\mathrm{T}}\left(A\Theta_S A^{\mathrm{T}} + \Theta_\varepsilon\right)^{-1}(O - A\mu_s - \mu_\varepsilon),$$
$$\Theta_S - \Theta_S A^{\mathrm{T}}\left(A\Theta_S A^{\mathrm{T}} + \Theta_\varepsilon\right)^{-1} A\Theta_S)$$

Poll 1

- X and Y are jointly Gaussian. Which of the following are true
  – Knowing X affects our expectation of Y, in all cases
  – Knowing X affects our expectation of Y if the two are correlated
  – Knowing X reduces the variance of the conditional distribution of Y by a value that depends on the observed X
  – Knowing X reduces the variance of Y by the same amount regardless of the observed X

- We are given that Y = AX + e, where X and e are Gaussian. Mark all that are true
  – Y and X are jointly Gaussian
  – The conditional distribution of X given Y is Gaussian
  – Knowing Y does not influence the variance of X, since Y is derived from X and not vice versa
  – Knowing Y does not influence the expected value of X since Y is derived from X and not vice versa

Poll 1

- X and Y are jointly Gaussian. Which of the following are true
  - Knowing X affects our expectation of Y, in all cases
  - **Knowing X affects our expectation of Y if the two are correlated**
  - Knowing X reduces the variance of the conditional distribution of Y by a value that depends on the observed X
  - **Knowing X reduces the variance of Y by the same amount regardless of the observed X**

- We are given that Y = AX + e, where X and e are Gaussian. Mark all that are true
  - **Y and X are jointly Gaussian**
  - **The conditional distribution of X given Y is Gaussian**
  - Knowing Y does not influence the variance of X, since Y is derived from X and not vice versa
  - Knowing Y does not influence the expected value of X since Y is derived from X and not vice versa

The little parable

You've been kidnapped

And blindfolded

You can only *hear* the car
You must find your way back home from wherever they drop you off

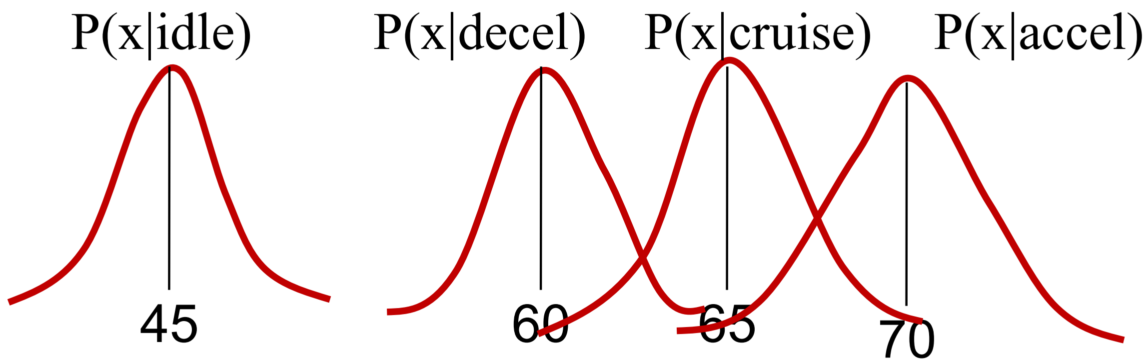
Kidnapped!

- Determine by only *listening* to a running automobile, if it is:
  - Idling; or
  - Travelling at constant velocity; or
  - Accelerating; or
  - Decelerating
- You only record energy level (SPL) in the sound
  - The SPL is measured once per second

What we know

- An automobile that is at rest can accelerate, or continue to stay at rest
- An accelerating automobile can hit a steady-state velocity, continue to accelerate, or decelerate
- A decelerating automobile can continue to decelerate, come to rest, cruise, or accelerate
- A automobile at a steady-state velocity can stay in steady state, accelerate or decelerate

What else we know



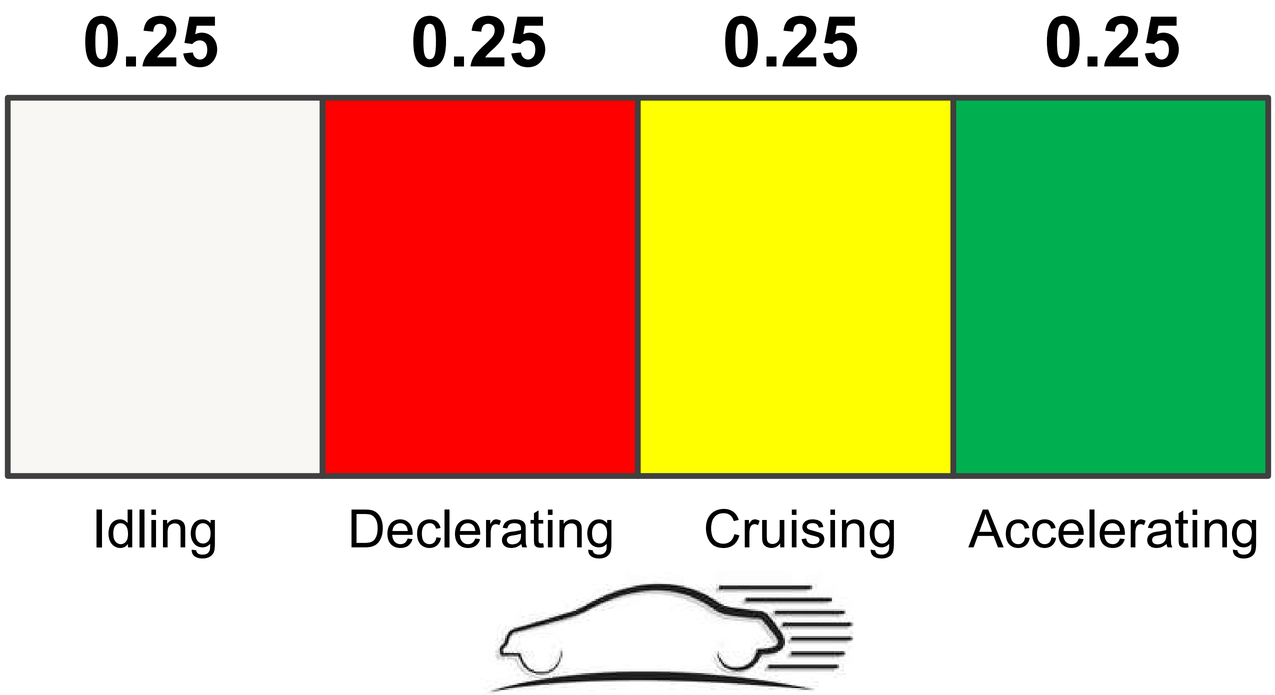
- The probability distribution of the SPL of the sound is different in the various conditions
  - As shown in figure
    - In reality, depends on the car
- The distributions for the different conditions overlap
  - Simply knowing the current sound level is not enough to know the state of the car

The Model!

	I	A	C	D
I	0.5	0.5	0	0
A	0	1/3	1/3	1/3
C	0	1/3	1/3	1/3
D	0.25	0.25	0.25	0.25

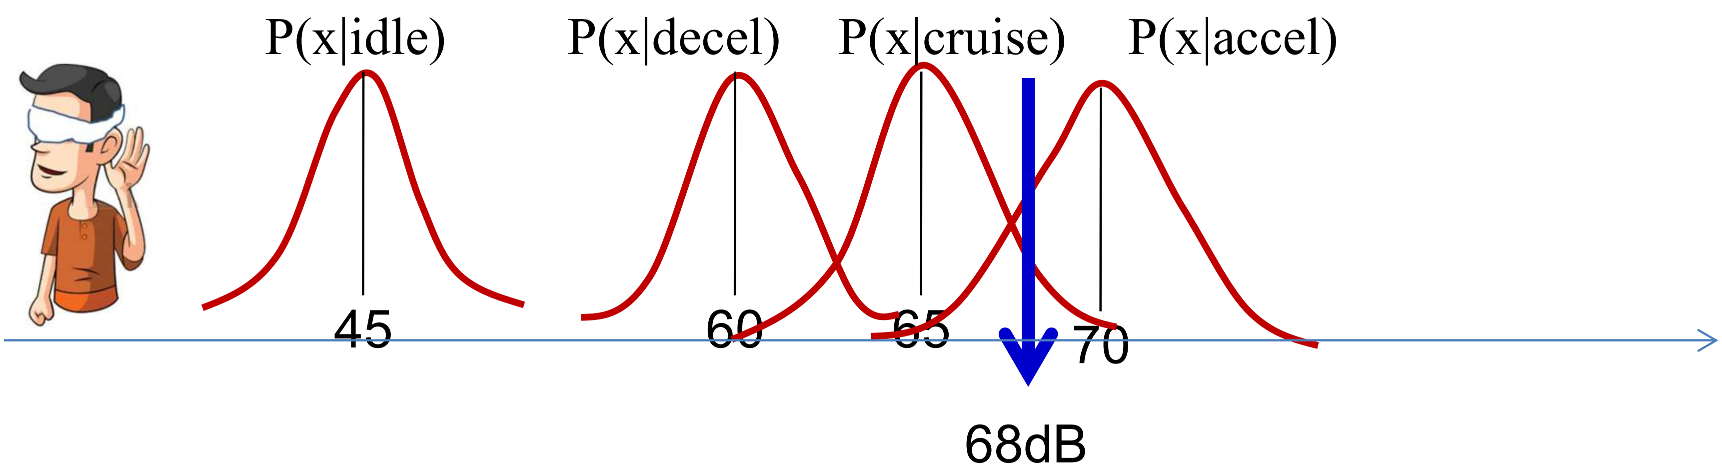
- The state-space model
  - Assuming all transitions from a state are equally probable
  - This is a Hidden Markov Model!

Estimating the state at T = 0-



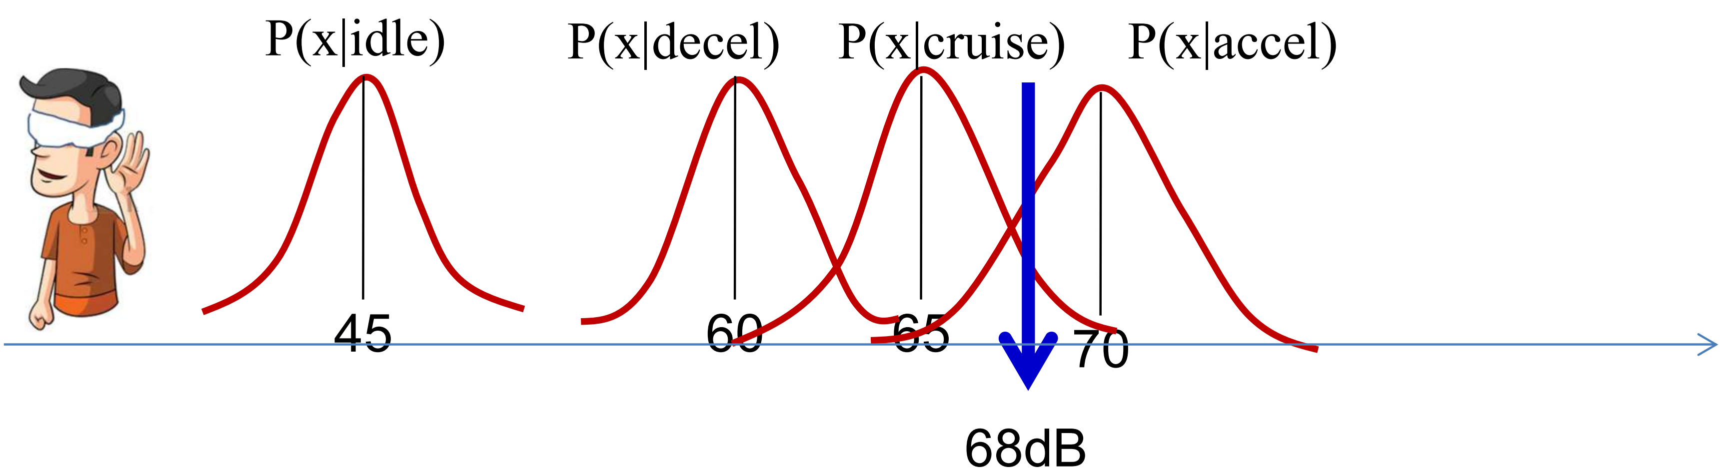
- A T=0, before the first observation, we know nothing of the state
  - Assume all states are equally likely

The first observation: T=0



- At T=0 you observe the sound level x_0 = 68dB SPL
  – The observation modifies our belief in the state of the system

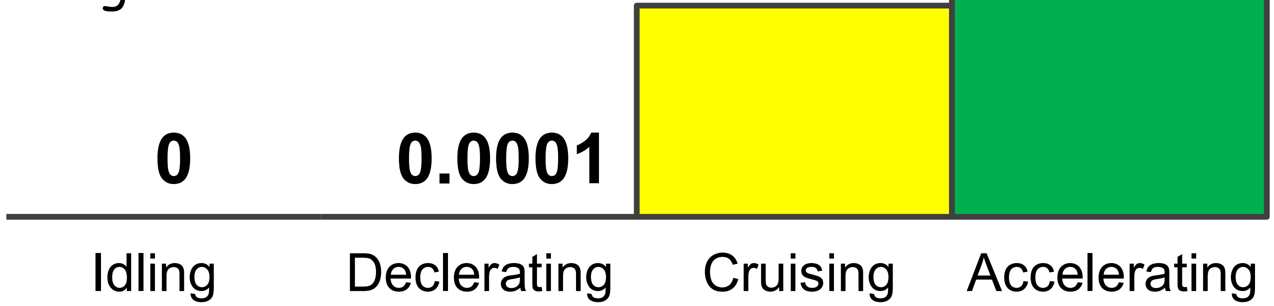
The first observation: T=0



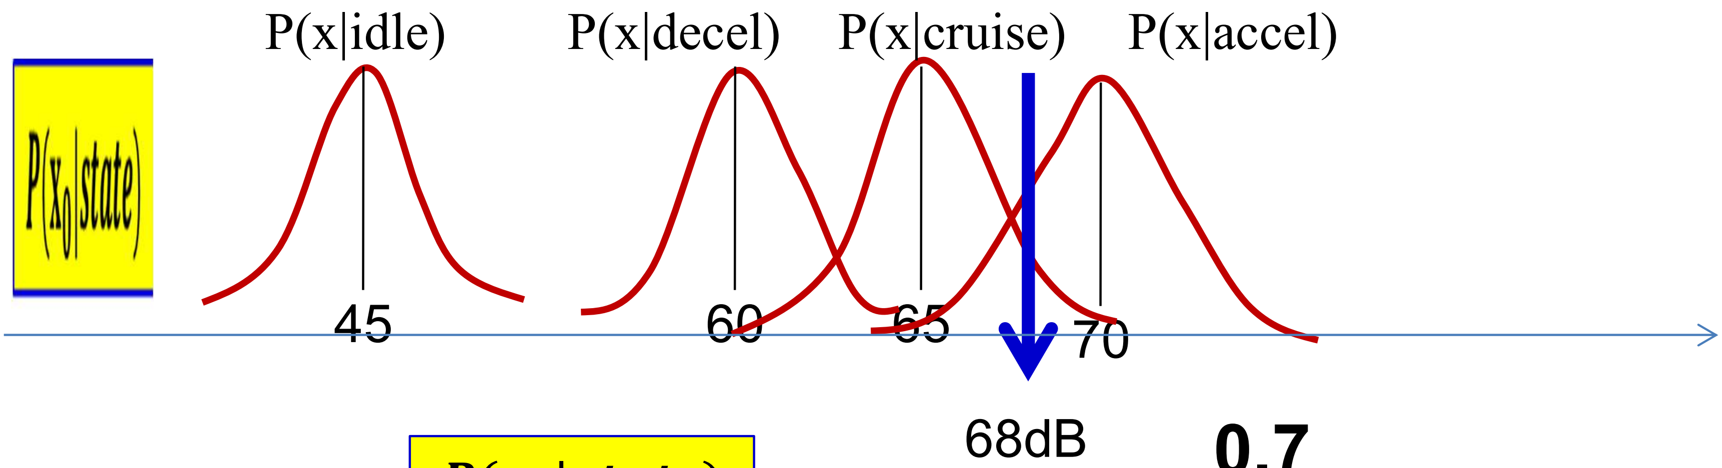
P(x|idle)	P(x|deceleration)	P(x|cruising)	P(x|acceleration)
0	0.0001	0.5	0.7

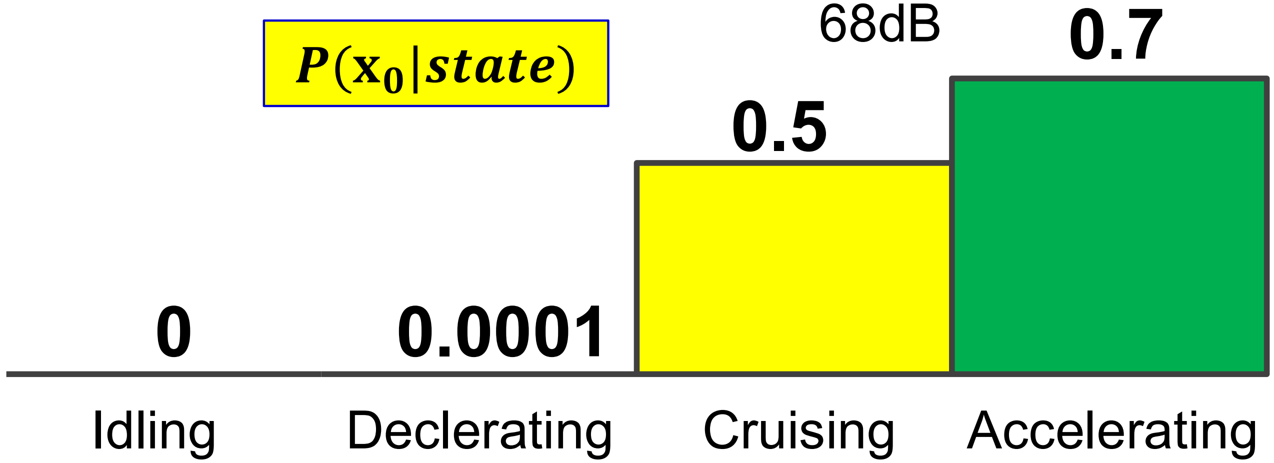
These don't have to sum to 1

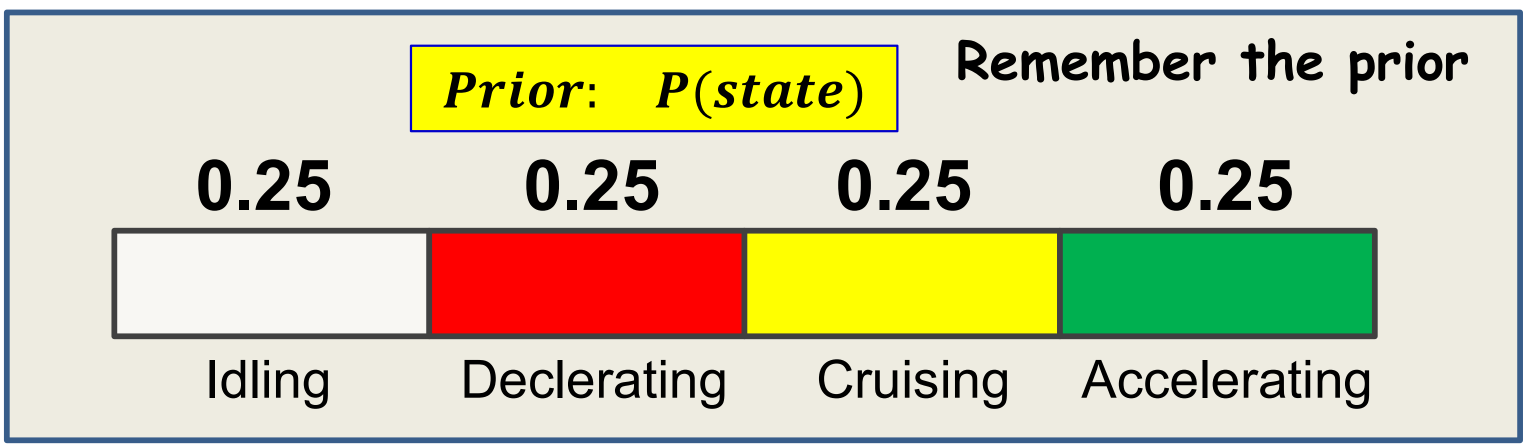
Can even be greater than 1!



The first observation: T=0





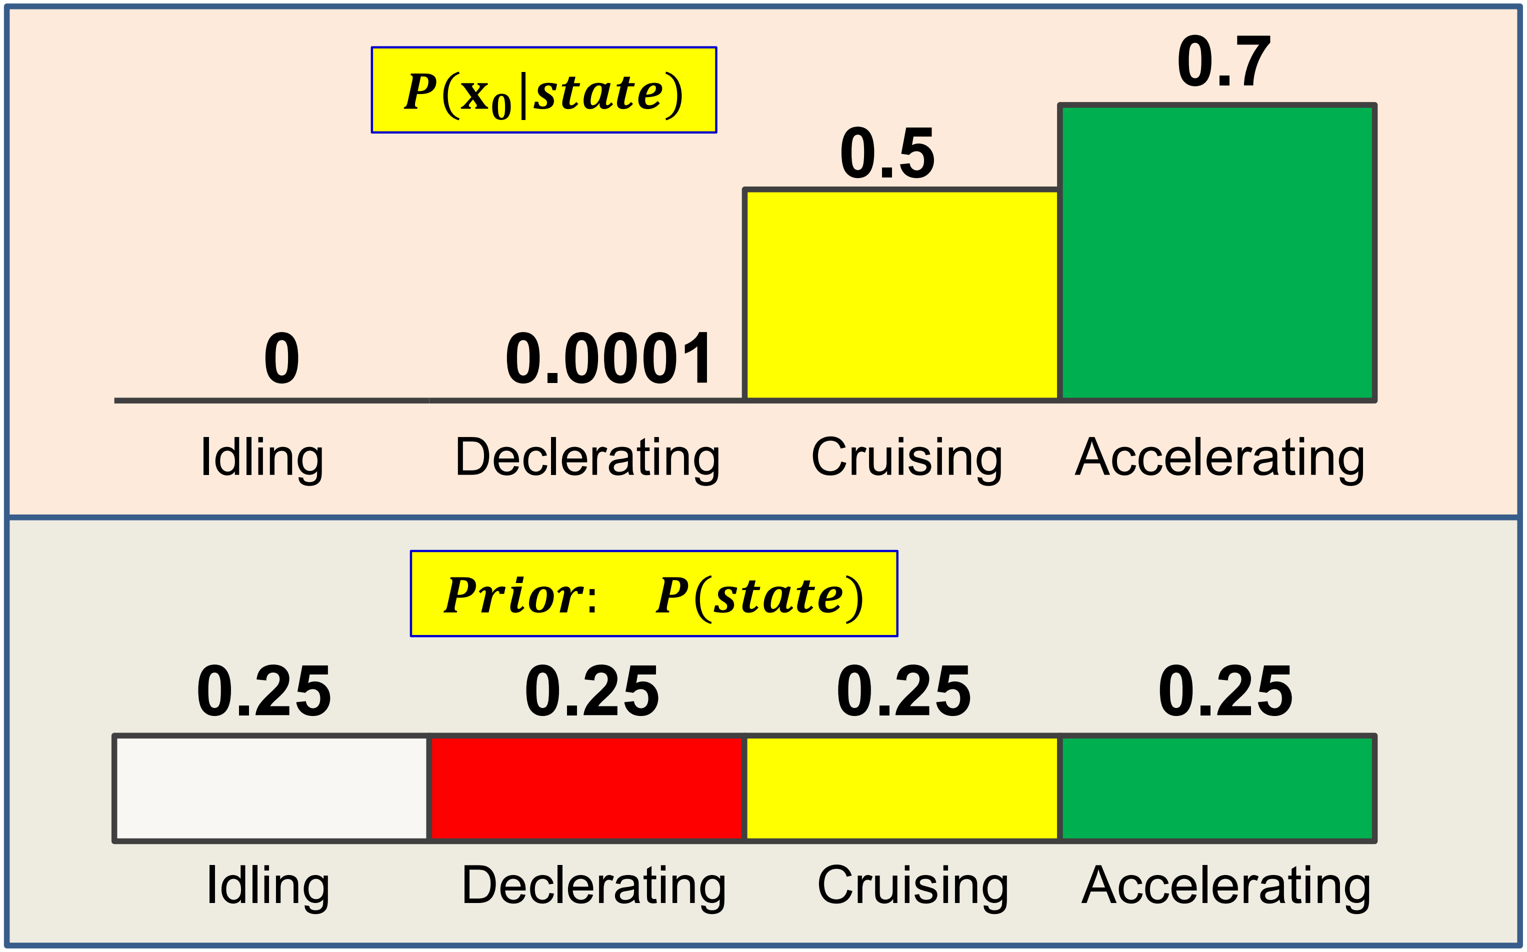


Estimating state *after* at observing $\mathbf{x}_0$

- Combine prior information about state and evidence from observation
- We want $P(state|\mathbf{x}_0)$
- We can compute it using Bayes rule as

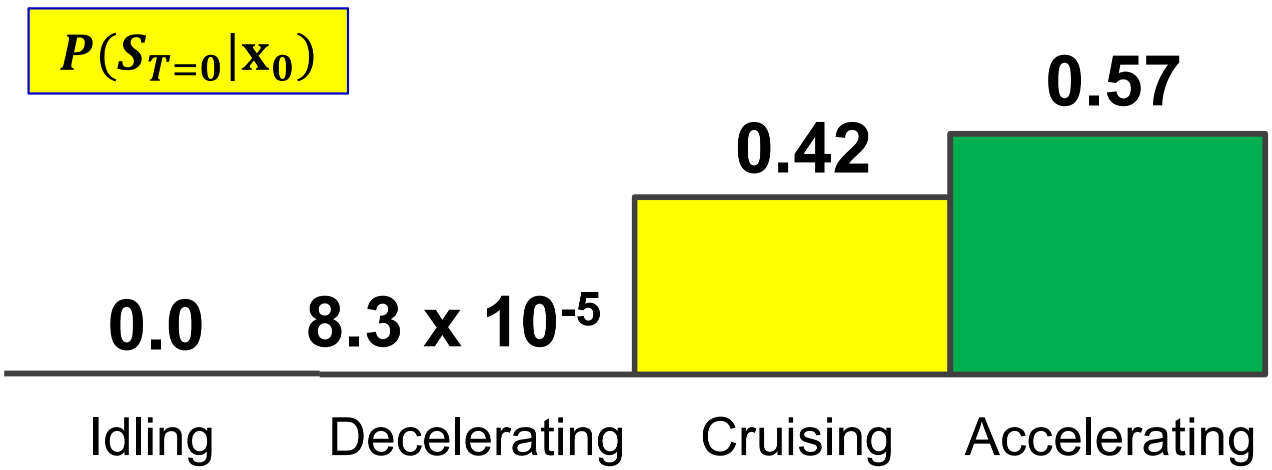
$$P(state|x_0) = \frac{P(state)P(\mathrm{x}_0|state)}{\sum_{state'} P(state')P(\mathrm{x}_0|state')}$$

The Posterior



- Multiply the two, term by term, and normalize them so that they sum to 1.0

Estimating the state at T = 0+



- At T=0, after the first observation x_0, we update our belief about the states
  - The first observation provided some evidence about the state of the system
  - It modifies our belief in the state of the system

Predicting the state at T=1

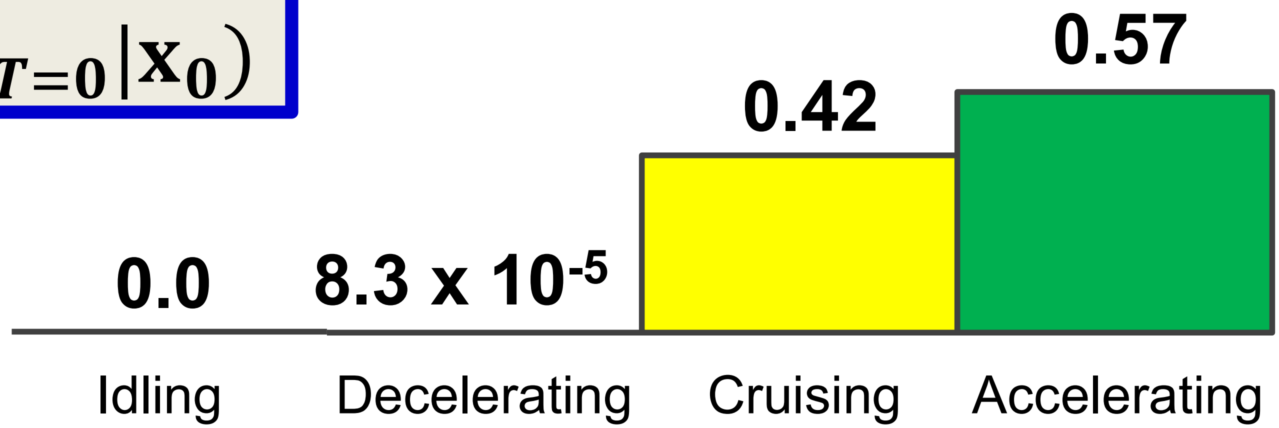
	I	A	C	D
I	0.5	0.5	0	0
A	0	1/3	1/3	1/3
C	0	1/3	1/3	1/3
D	0.25	0.25	0.25	0.25

- Predicting the probability of idling at T=1
  - $P(idling \mid idling) = 0.5;$
  - $P(idling \mid deceleration) = 0.25$
  - $P(idling \text{ at T=1} \mid x_0) =$
    $P(I_{T=0}|x_0)\ P(I|I) + P(D_{T=0}|x_0)\ P(I|D) = 2.1 \times 10^{-5}$

- In general, for any state S
  - $P(S_{T=1}|\mathbf{x}_0) = \sum_{S_{T=0}} P(S_{T=0}|\mathbf{x}_0) P(S_{T=1}|S_{T=0})$

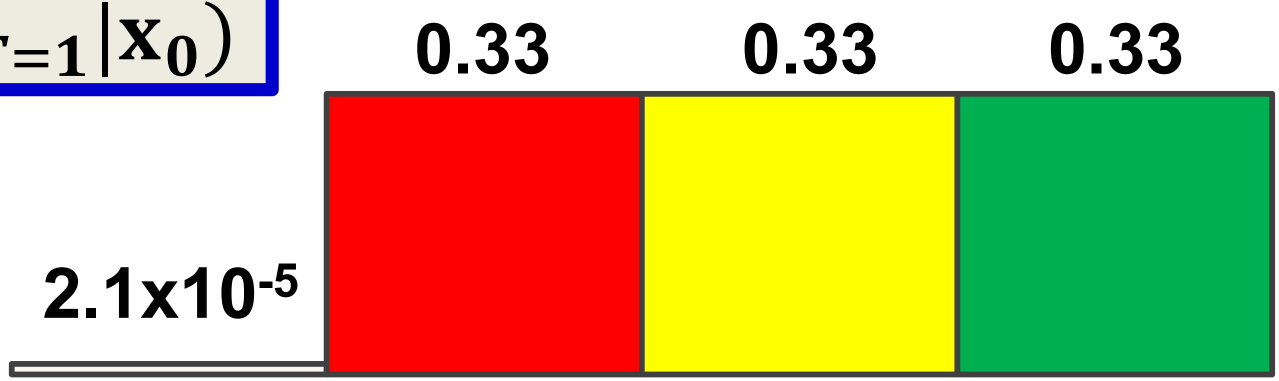
Predicting the state at T = 1

$$\boxed{P(S_{T=0}|\mathbf{x}_0)}$$



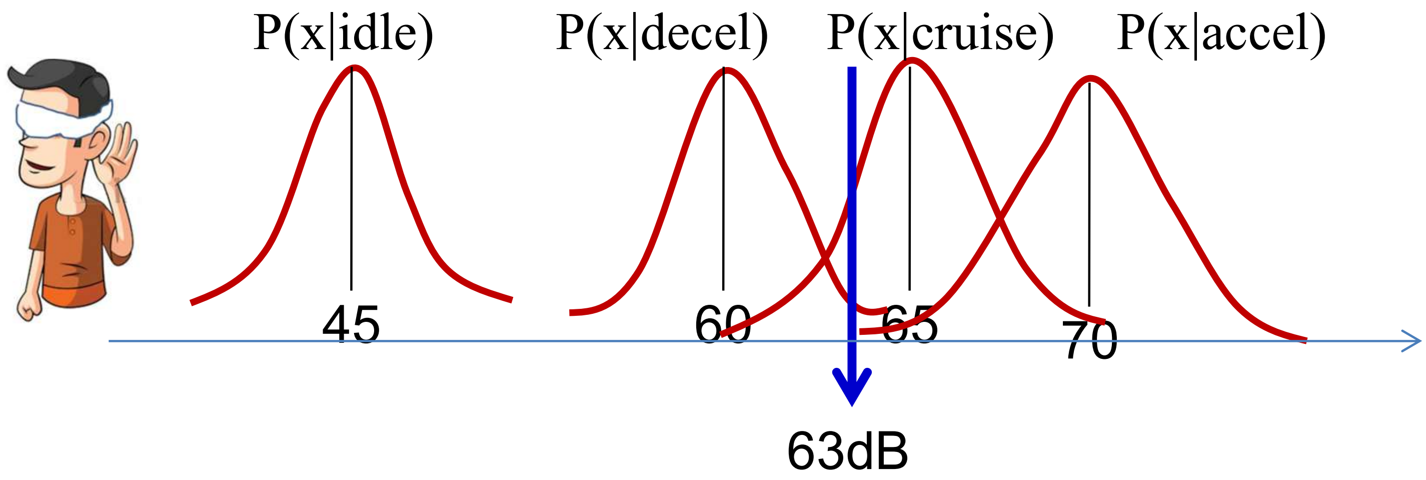
$$P(S_{T=1}|\mathbf{x}_0) = \sum_{S_{T=0}} P(S_{T=0}|\mathbf{x}_0)P(S_{T=1}|S_{T=0})$$

$$\boxed{P(S_{T=1}|\mathbf{x}_0)}$$



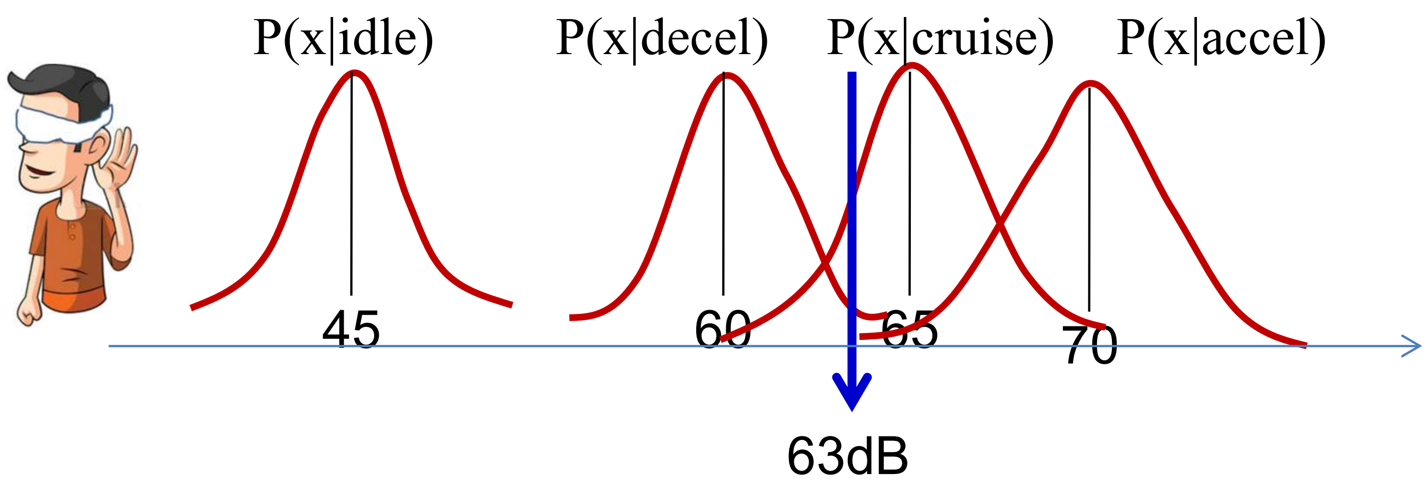
Rounded.
In reality, they sum to 1.0

Updating after the observation at T=1



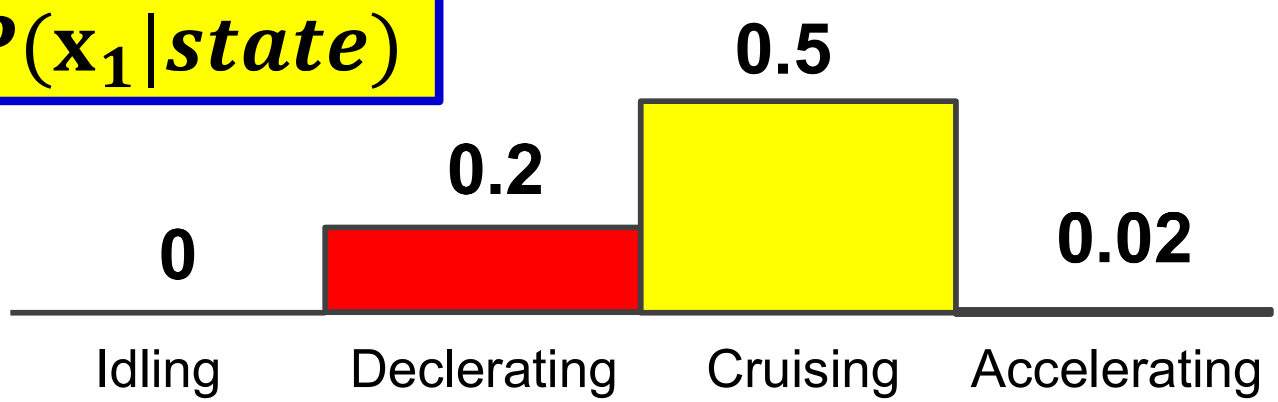
- At T=1 we observe x_1 = 63dB SPL

Updating after the observation at T=1

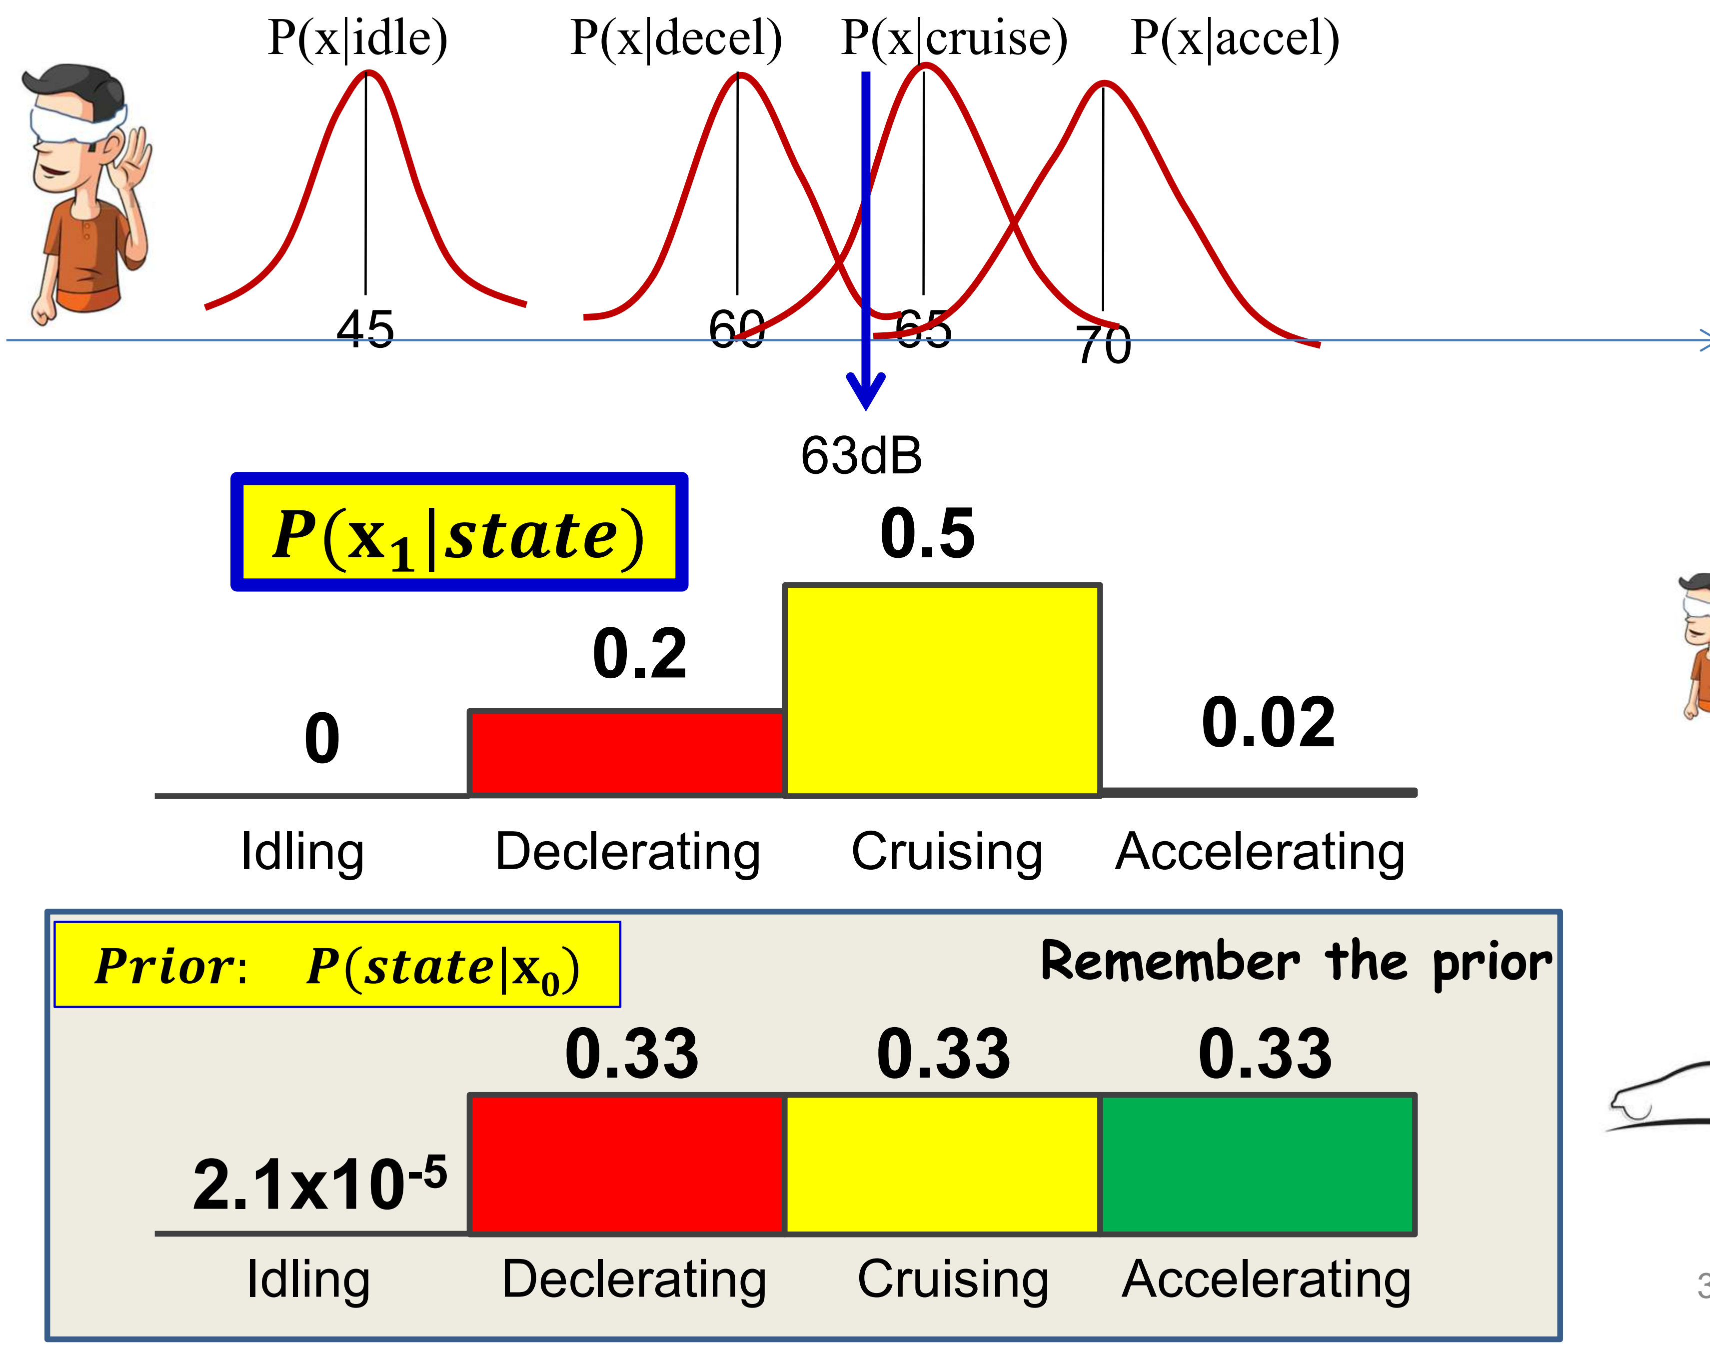


P(x|idle)	P(x|deceleration)	P(x|cruising)	P(x|acceleration)
0	0.2	0.5	0.01

$\boxed{P(x_1|state)}$



The second observation: T=1



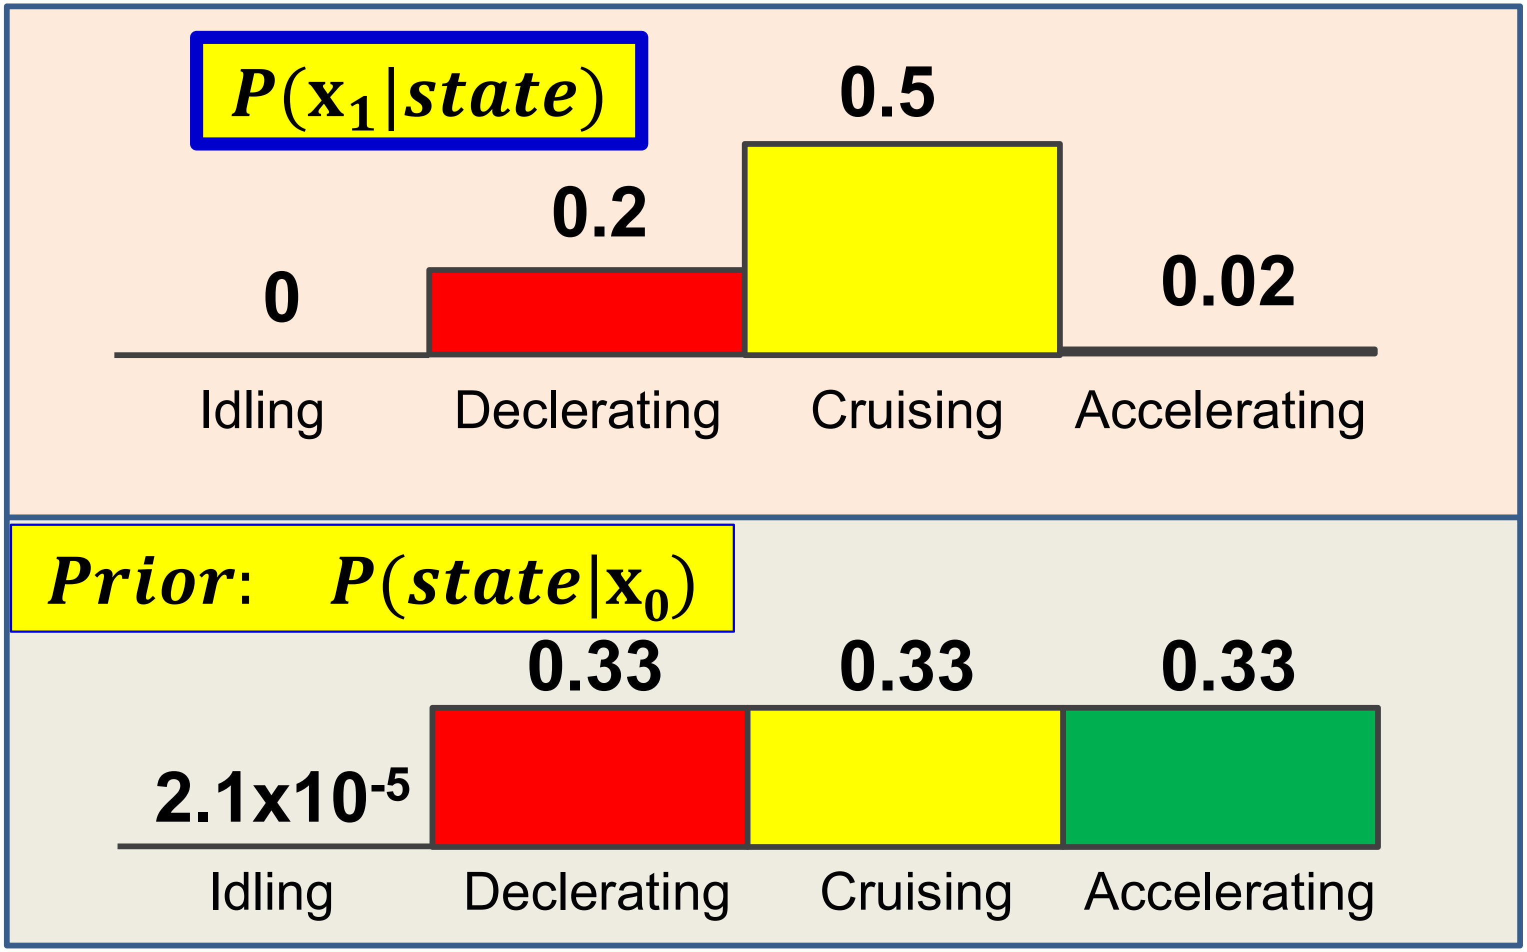
Estimating state *after* at observing $\mathbf{x}_1$

- Combine prior information from the observation at time T=0, AND evidence from observation at T=1 to estimate ***state*** at T=1

- We want $P(state|\mathbf{x}_0, \mathbf{x}_1)$
- We can compute it using Bayes rule as

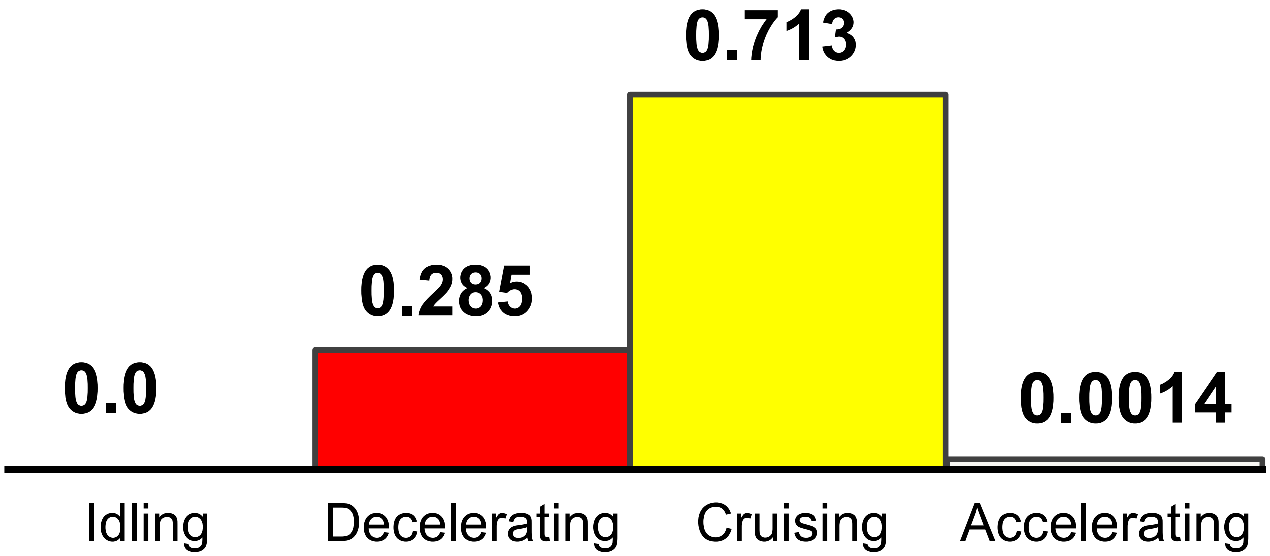
$$P(state|\mathbf{x}_0, \mathbf{x}_1) = \frac{P(state|\mathbf{x}_0)P(\mathbf{x}_1|state)}{\sum_{state'} P(state'|\mathbf{x}_0)P(\mathbf{x}_1|state')}$$

The Posterior at T = 1



- Multiply the two, term by term, and normalize them so that they sum to 1.0

Estimating the state at T = 1+



- The updated probability at T=1 incorporates information from both x_0 and x_1
  - It is NOT a local decision based on x_1 alone
  - Because of the Markov nature of the process, the state at T=0 affects the state at T=1
    - x_0 provides evidence for the state at T=1

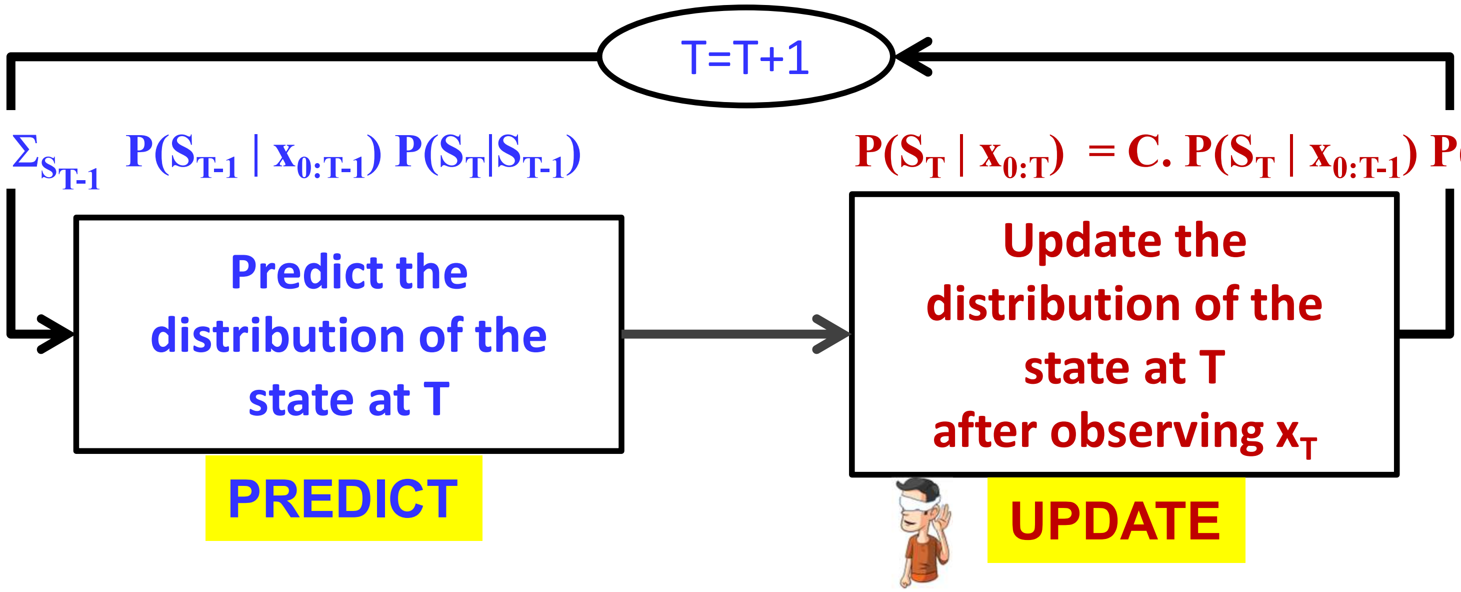
Overall Process

Time	Computation
T=0- : A priori probability	$P(S_0) = P(S)$
T = 0+: Update after X_0	$P(S_0 \mid X_0) = C.P(S_0)P(X_0 \mid S_0)$
T=1- (Prediction before X_1)	$P(S_1 \mid X_0) = \sum_{S_0} P(S_1 \mid S_0)P(S_0 \mid X_0)$
T = 1+: Update after X_1	$P(S_1 \mid X_{0:1}) = C.P(S_1 \mid X_0)P(X_1 \mid S_1)$
T=2- (Prediction before X_2)	$P(S_2 \mid X_{0:1}) = \sum_{S_1} P(S_2 \mid S_1)P(S_1 \mid X_{0:1})$
T = 2+: Update after X_2	$P(S_2 \mid X_{0:2}) = C.P(S_2 \mid X_{0:1})P(X_2 \mid S_2)$
…	…
T= t- (Prediction before X_t)	$P(S_t \mid X_{0:t-1}) = \sum_{S_{t-1}} P(S_t \mid S_{t-1})P(S_{t-1} \mid X_{0:t-1})$
T = t+: Update after X_t	$P(S_t \mid X_{0:t}) = C.P(S_t \mid X_{0:t-1})P(X_t \mid S_t)$

Overall procedure

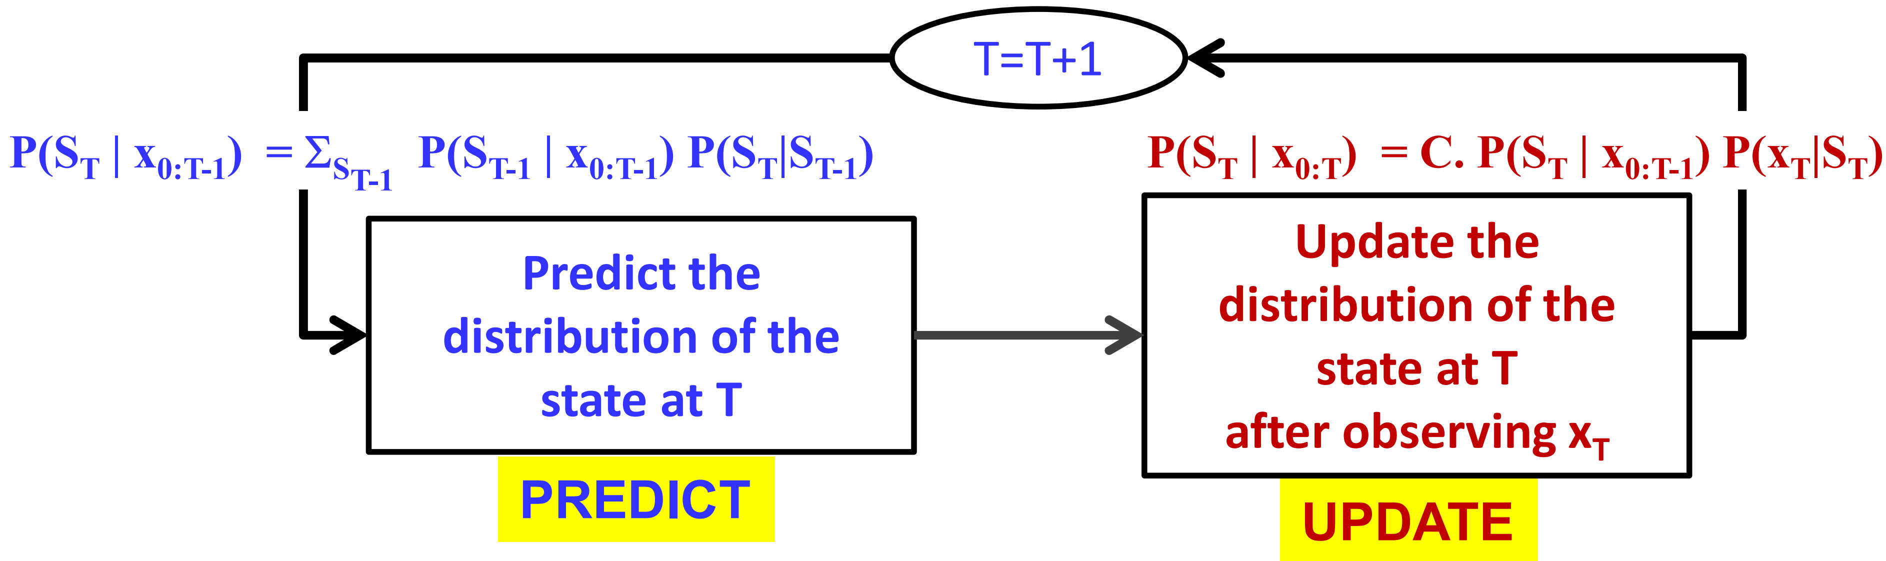
$P(S_T \mid x_{0:T-1}) = \Sigma_{S_{T-1}} P(S_{T-1} \mid x_{0:T-1}) P(S_T|S_{T-1})$

$P(S_T \mid x_{0:T}) = C.\, P(S_T \mid x_{0:T-1}) P(x_T|S_T)$



- At T=0 the predicted state distribution is the initial state probability
- At each time T, the current estimate of the distribution over states considers *all* observations $x_0 \ldots x_T$
  - A natural outcome of the Markov nature of the model
- The prediction+update is identical to the forward computation for HMMs to within a normalizing constant

Comparison to Forward Algorithm



- Forward Algorithm:
  - $P(x_{0:T},S_T) = P(x_T|S_T) \Sigma_{S_{T-1}} P(x_{0:T-1}, S_{T-1}) P(S_T|S_{T-1})$

PREDICT

UPDATE

- Normalized:
  - $P(S_T|x_{0:T}) = (\Sigma_{S'_T} P(x_{0:T},S'_T))^{-1} P(x_{0:T},S_T) = C\ P(x_{0:T},S_T)$

Decomposing the Algorithm

$$P(S_t, X_{0:t}) = P(X_t|S_t) \sum_{S_{t-1}} P(S_t|S_{t-1}) P(S_{t-1}, X_{0:t-1})$$

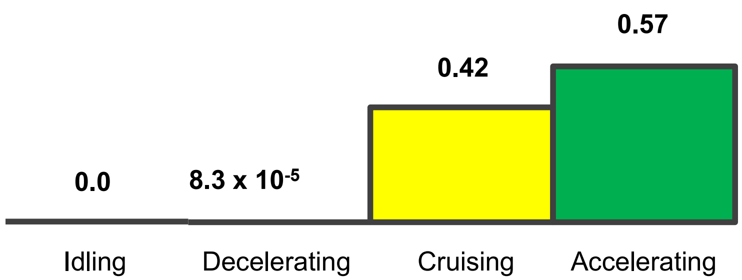
Predict: $P(S_t|X_{0:t-1}) = \sum_{S_{t-1}} P(S_t|S_{t-1}) P(S_{t-1}|X_{0:t-1})$

Update: $P(S_t|X_{0:t}) = \frac{P(S_t|X_{0:t-1}) P(X_t|S_t)}{\sum_S P(S|X_{0:t-1}) P(X_t|S)}$

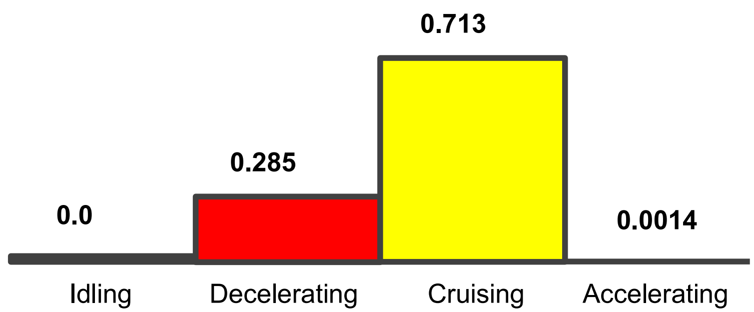
Estimating a Unique state

- What we have estimated is a *distribution* over the states
- If we had to guess ***a*** state, we would pick the most likely state from the distributions

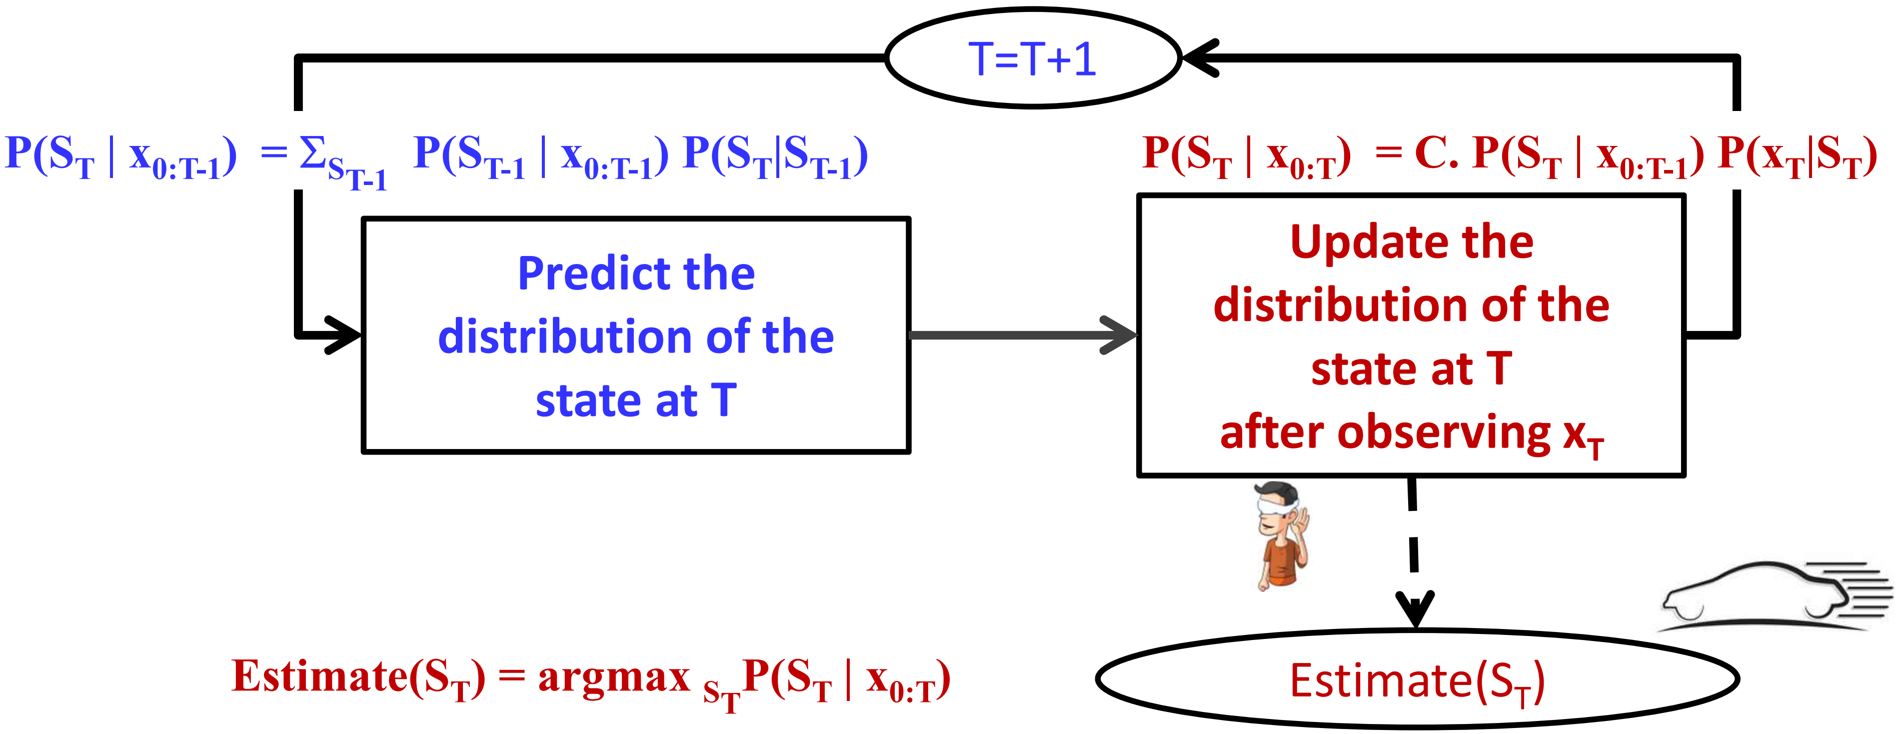
- State(T=0) = Accelerating



- State(T=1) = Cruising

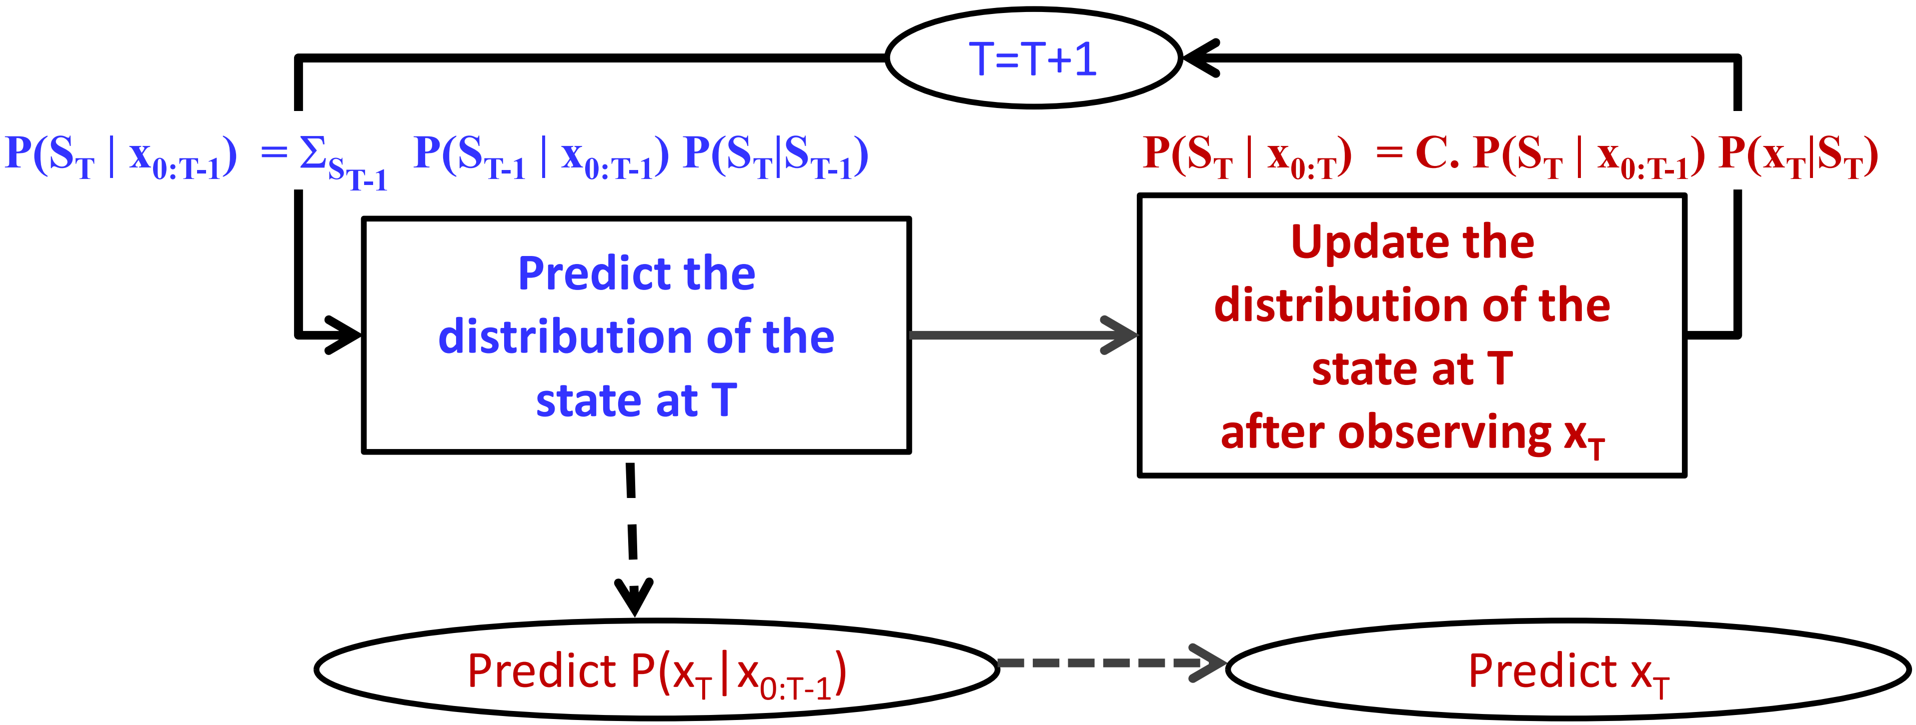


Estimating the *state*



- The state is estimated from the updated distribution
  - The updated distribution is propagated into time, not the state

Predicting the *next observation*



- The probability distribution for the observations at the next time is a mixture:
- $P(X_t|X_{0:t-1}) = \sum_{S_t} P(X_t|S_t)P(S_t|X_{0:t-1})$
- The actual observation can be predicted from $P(x_T|x_{0:T-1})$

Predicting the next observation

- Can use any of the various estimators of x_T from $P(x_T|x_{0:T-1})$
- MAP estimate:
  - $\arg\max_{x_T} P(x_T|x_{0:T-1})$
- MMSE estimate:
  - $\text{Expectation}(x_T|x_{0:T-1})$

Difference from Viterbi decoding

- Estimating only the *current* state at any time
  - Not the state sequence
  - Although we are considering all past observations
- The most likely state at T and T+1 may be such that there is no valid transition between S_T and S_{T+1}

Poll 2

- To find your way back home…
  - At each time t you *predict* your beliefs about what your state will be at the *next time t+1* based on all you have observed until now (time t)
  - At each time t, you *update* your beliefs about the state at t, that you made when still at t-1, based on the latest observation O(t)
  - At each time t you predict your belief at the state at t+1, and then update your belief after observing O(t+1)
  - At each time you predict the distribution of the state at t+1, and then update your predicted distribution based on O(t+1)
  - Your guess for the actual state must be derived from the estimated distribution for the state

Poll 2

- To find your way back home…
  - **At each time t you *predict* your beliefs about what your state will be at the *next time t+1* based on all you have observed until now (time t)**
  - **At each time t, you *update* your beliefs about the state at t, that you made when still at t-1, based on the latest observation O(t)**
  - At each time t you predict the actual state at t+1, and then update your guess for the state after observing O(t+1)
  - **At each time you predict the distribution of the state at t+1, and then update your predicted distribution based on O(t+1)**
  - **Your guess for the actual state must be derived from the estimated distribution for the state**

A *continuous* state model

- HMM assumes a very coarsely quantized state space
  - Idling / accelerating / cruising / decelerating
- Actual state can be finer
  - Idling, accelerating at various rates, decelerating at various rates, cruising at various speeds
- Solution: Many more states (one for each acceleration /deceleration rate, crusing speed)?
- Solution: A *continuous* valued state

Tracking and Prediction: The wind and the target

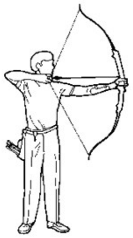
- Aim: measure wind velocity
- Using a noisy wind speed sensor
  - E.g. arrows shot at a target

- **State:** Wind speed at time t depends on speed at time t-1

$$S_t = S_{t-1} + \epsilon_t$$

- **Observation:** Arrow position at time *t* depends on wind speed at time *t*

$$Y_t = AS_t + \gamma_t$$



The real-valued state model

- A state equation describing the dynamics of the system

$$s_t = f(s_{t-1}, \varepsilon_t)$$

  - s_t is the state of the system at time t
  - ε_t is a driving function, which is assumed to be random
- The state of the system at any time depends only on the state at the previous time instant and the driving term at the current time

- An observation equation relating state to observation

$$o_t = g(s_t, \gamma_t)$$

  - o_t is the observation at time t
  - γ_t is the noise affecting the observation (also random)
- The observation at any time depends only on the current state of the system and the noise

States are still “hidden”

$$s_t = f(s_{t-1}, \varepsilon_t)$$

$$o_t = g(s_t, \gamma_t)$$

- The state is a continuous valued parameter that is not directly seen
  - The state is the position of the automobile or the star
- The observations are dependent on the state and are the only way of knowing about the state
  - Sensor readings (for the automobile) or recorded image (for the telescope)

Statistical Prediction and Estimation

- Given an *a priori* probability distribution for the state
  - $P_0(s)$: Our belief in the state of the system before we observe any data
    - Probability of state of navlab
    - Probability of state of stars
- Given a sequence of observations $o_0..o_t$
- Estimate state at time t

Prediction and update at t = 0

- Prediction
  - Initial probability distribution for state
  - $P(s_0) = P_0(s_0)$
- Update:
  - Then we observe o_0
  - We must update our belief in the state

$$P(s_0 \mid o_0) = \frac{P(s_0)P(o_0 \mid s)}{P(o_0)} = \frac{P_0(s_0)P(o_0 \mid s_0)}{P(o_0)}$$

- $P(s_0|o_0) = C.P_0(s_0)P(o_0|s_0)$

Prediction and update at t = 0

- Prediction
  - Initial probability distribution for state
  - $P(s_0) = P_0(s_0)$
- Update:
  - Then we observe o_0
  - We must update our belief in the state

$$P(s_0 \mid o_0) = \frac{P(s_0)P(o_0 \mid s)}{P(o_0)} = \frac{P_0(s_0)P(o_0 \mid s_0)}{P(o_0)}$$

- $P(s_0|o_0) = C.P_0(s_0)P(o_0|s_0)$

The observation probability: P(o|s)

- $o_t = g(s_t, \gamma_t)$
  - This is a (possibly many-to-one) stochastic function of state s_t and noise γ_t
  - Noise γ_t is random. Assume it is the same dimensionality as o_t

- Let $P_\gamma(\gamma_t)$ be the probability distribution of γ_t
- Let $\{\gamma : g(s_t, \gamma) = o_t\}$ be all γ that result in o_t

$$P(o_t \mid s_t) = \sum_{\gamma : g(s_t, \gamma) = o_t} \frac{P_\gamma(\gamma)}{|J_\gamma(g(s_t, \gamma))|}$$

The observation probability

- $P(o|s) = ?$ $o_t = g(s_t, \gamma_t)$

$$P(o_t \mid s_t) = \sum_{\gamma : g(s_t,\gamma)=o_t} \frac{P_\gamma(\gamma)}{|J_\gamma(g(s_t,\gamma))|}$$

- The J is a Jacobian

$$|J_\gamma(g(s_t,\gamma))| = \begin{vmatrix} \frac{\partial o_t(1)}{\partial \gamma(1)} & \cdots & \frac{\partial o_t(1)}{\partial \gamma(n)} \\ \vdots & \ddots & \vdots \\ \frac{\partial o_t(n)}{\partial \gamma(1)} & \cdots & \frac{\partial o_t(n)}{\partial \gamma(n)} \end{vmatrix}$$

- For scalar functions of scalar variables, it is simply a derivative: $|J_\gamma(g(s_t,\gamma))| = \left|\frac{\partial o_t}{\partial \gamma}\right|$

Predicting the next state at t=1

- Given P(s_0|o_0), what is the probability of the state at t=1

$$P(s_1 | o_0) = \int_{\{s_0\}} P(s_1, s_0 | o_0) ds_0 = \int_{\{s_0\}} P(s_1 | s_0) P(s_0 | o_0) ds_0$$

- State progression function:

$$s_t = f(s_{t-1}, \varepsilon_t)$$

  - ε_t is a driving term with probability distribution $P_\varepsilon(\varepsilon_t)$

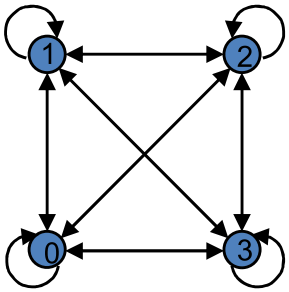
- P(s_t|s_{t-1}) can be computed similarly to P(o|s)
  - P(s_1|s_0) is an instance of this

And moving on

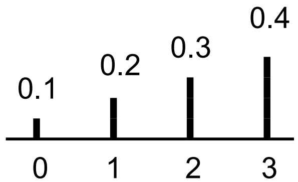
- $P(s_1|o_0)$ is the predicted state distribution for t=1
- Then we observe o_1
  - We must update the probability distribution for s_1
  - $P(s_1|o_{0:1}) = CP(s_1|o_0)P(o_1|s_1)$

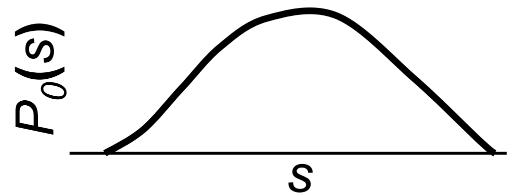
- We can continue on

Discrete vs. Continuous state systems



$\pi =$





$$s_t = f(s_{t-1}, \varepsilon_t)$$

$$o_t = g(s_t, \gamma_t)$$

Prediction at time 0:

$$P(S_0) = \pi(S_0) \qquad\qquad P(S_0) = P_0(S_0)$$

Update after O_0:

$$P(S_0|O_0) = C.\pi(S_0)P(O_0|S_0) \qquad\qquad P(S_0|O_0) = C.P(S_0)P(O_0|S_0)$$

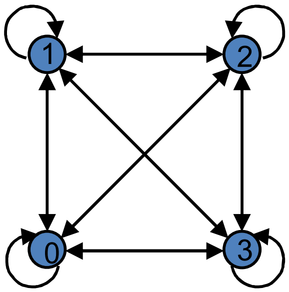
Prediction at time 1:

$$P(S_1|O_0) = \sum_{S_0} P(S_0|O_0)P(S_1|S_0) \qquad\qquad P(S_1|O_0) = \int_{-\infty}^{\infty} P(S_0|O_0)P(S_1|S_0)dS_0$$

Update after O_1:

$$P(S_1|O_{0:1}) = C.P(S_1|O_0)P(O_1|S_1) \qquad\qquad P(S_1|O_{0:1}) = C.P(S_1|O_0)P(O_1|S_1)$$

Discrete vs. Continuous State Systems



$\pi =$

$$s_t = f(s_{t-1}, \varepsilon_t)$$

$$o_t = g(s_t, \gamma_t)$$

Prediction at time t:

$$P(S_t|O_{0:t-1}) = \sum_{S_{t-1}} P(S_{t-1}|O_{0:t-1})P(S_t|S_{t-1})$$

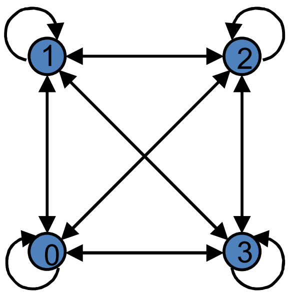
$$P(S_t|O_{0:t-1}) = \int_{-\infty}^{\infty} P(S_{t-1}|O_{0:t-1})P(S_t|S_{t-1})dS_{t-1}$$

Update after observing O_t:

$$P(S_t|O_{0:t}) = C.P(S_t|O_{0:t-1})P(O_t|S_t)$$

$$P(S_t|O_{0:t}) = C.P(S_t|O_{0:t-1})P(O_t|S_t)$$

Discrete vs. Continuous State Systems



$\pi =$ 

$$s_t = f(s_{t-1}, \varepsilon_t)$$

$$o_t = g(s_t, \gamma_t)$$

Parameters		
Initial state prob.	π	$P(s)$
Transition prob	$P(s_t = j \| s_{t-1} = i)$	$P(s_t \| s_{t-1})$
Observation prob	$P(O \| s)$	$P(O \| s)$

Special case: Linear Gaussian model

$$s_t = A_t s_{t-1} + \varepsilon_t$$

$$P(\varepsilon) = \frac{1}{\sqrt{(2\pi)^d \, |\Theta_\varepsilon|}} \exp\left(-0.5(\varepsilon - \mu_\varepsilon)^T \Theta_\varepsilon^{-1} (\varepsilon - \mu_\varepsilon)\right)$$

$$o_t = B_t s_t + \gamma_t$$

$$P(\gamma) = \frac{1}{\sqrt{(2\pi)^d \, |\Theta_\gamma|}} \exp\left(-0.5(\gamma - \mu_\gamma)^T \Theta_\gamma^{-1} (\gamma - \mu_\gamma)\right)$$

- A *linear* state dynamics equation
  - Probability of state driving term ε is Gaussian
  - Sometimes viewed as a driving term μ_ε and additive zero-mean noise
- A *linear* observation equation
  - Probability of observation noise γ is Gaussian
- A_t, B_t and Gaussian parameters assumed known
  - May vary with time

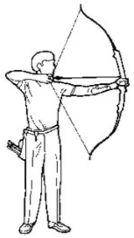
Linear model example
The wind and the target

- **State:** Wind speed at time t depends on speed at time t-1

$$S_t = S_{t-1} + \epsilon_t$$

- **Observation:** Arrow position at time t depends on wind speed at time t

$$O_t = BS_t + \gamma_t$$



Model Parameters: The initial state probability

$$P_0(s) = \frac{1}{\sqrt{(2\pi)^d \, |R|}} \exp\left(-0.5(s-\bar{s})R^{-1}(s-\bar{s})^T\right)$$

$$P_0(s) = Gaussian(s; \bar{s}, R)$$

- We also assume the *initial* state distribution to be Gaussian
  - Often assumed zero mean

$$s_t = A_t s_{t-1} + \varepsilon_t$$

$$o_t = B_t s_t + \gamma_t$$

Model Parameters: The observation probability

$$o_t = B_t s_t + \gamma_t$$

$$P(\gamma) = Gaussian(\gamma; \mu_\gamma, \Theta_\gamma)$$

$$P(o_t \mid s_t) = Gaussian(o_t; \mu_\gamma + B_t s_t, \Theta_\gamma)$$

- The probability of the observation, given the state, is simply the probability of the noise, with the mean shifted
  - Since the only uncertainty is from the noise
- The new mean is the mean of the distribution of the noise + the value of the observation in the absence of noise

Model Parameters: State transition probability

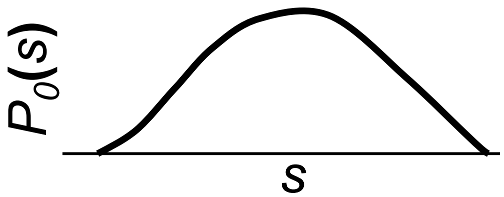
$$s_{t+1} = A_t s_t + \varepsilon_t$$

$$P(\varepsilon) = Gaussian(\varepsilon; \mu_\varepsilon, \Theta_\varepsilon)$$

$$P(s_{t+1} \mid s_t) = Gaussian(s_t; \mu_\varepsilon + A_t s_t, \Theta_\varepsilon)$$

- The probability of the state at time t, given the state at t-1, is simply the probability of the driving term, with the mean shifted

Continuous state systems



$$s_{t+1} = A_t s_t + \varepsilon_t$$

$$o_t = B_t s_t + \gamma_t$$

Prediction at time 0:

- Prediction (based on state equation)

$$s_t = A_t s_{t-1} + \varepsilon_t$$

$$\bar{s}_t = A_t \hat{s}_{t-1} + \mu_\varepsilon$$

$$R_t = \Theta_\varepsilon + A_t \hat{R}_{t-1} A_t^T$$

- Update (using observation and observation equation)

$$o_t = B_t s_t + \gamma_t$$

$$K_t = R_t B_t^T \left(B_t R_t B_t^T + \Theta_\gamma \right)^{-1}$$

$$\hat{s}_t = \bar{s}_t + K_t \left(o_t - B_t \bar{s}_t - \mu_\gamma \right)$$

$$\hat{R}_t = \left(I - K_t B_t \right) R_t$$

Explaining the Kalman Filter

- Prediction

$$\bar{s}_t = A_t \hat{s}_{t-1} + \mu_\varepsilon$$

$$R_t = \Theta_\varepsilon + A_t \hat{R}_{t-1} A_t^T$$

$$s_t = A_t s_{t-1} + \varepsilon_t$$

$$o_t = B_t s_t + \gamma_t$$

- The Kalman filter can be explained intuitively without working through the math

$$\hat{s}_t = \bar{s}_t + K_t \left(o_t - B_t \bar{s}_t - \mu_\gamma \right)$$

$$\hat{R}_t = \left(I - K_t B_t \right) R_t$$
